LIST OF FIGURES

Figure 1. Major categorical causal groupings associated with aquatic life impairments in the upper Des Plaines River mainstem in 2020 based on the number of observations (upper) and weighted observations (lower), the latter based on the narrative rating of IPS threshold exceedances (very poor = 5, poor = 3, and fair = 1).	4
Figure 2. Location of biological, chemical, and habitat sampling sites in the DRWW study area in 2020. Site codes correspond to the sites listed in Table 5.	16
Figure 3. The hierarchy of administrative and environmental indicators which can be used to support monitoring and assessment, reporting, and an evaluation of the effectiveness of pollution controls on a receiving stream. This is attened after a model developed by U.S. EPA (1995a,b) and enhanced by Karr and Yoder (2004).	24
Figure 4. Daily flow measured at the USGS gauge on the Des Plaines River (USGS 05528500) near Gurnee, IL during the calendar years 2016, 2018, and 2020. The horizontal lines are the flood stage, 75 th percentile, 50 th percentile, and the seven-day, ten year (Q _{7,10}) critical low flows. The span of biological collection in 2020 is indicated by shaded bars.	26

Figure 5. Proportions of effluent flow (MGD) and pollutant loadings (lbs./day) discharged by seven (7) major WWTPs to the mainstem Des Plaines River in 2020. Proportions and loadings are based on the annual averages of each parameter. Discharges are listed in order from upstream to downstream in the inset table (bottom). 28

Figure 6. Dissolved oxygen (D.O.) concentrations (mg/L) measured continuously by Datasondes deployed for 3-4 day periods during August 21-24 and 24-27, 2020 at 13 locations in the 2020 and at 3 long term locations operated by DRWW. Box-and-whisker plots show the minimum, maximum, 25th and 75th percentiles, median, and outliers (>2 interquartile ranges from the median) values. The IEPA August-February minimum (3.5 mg/L) and the 7-day average D.O. criteria are shown by solid and dashed lines. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each. 37

Figure 7. pH values measured continuously by Datasondes deployed for 3-4 day periods during August 21-24 and 24-27, 2020 at 12 locations and continuous data at three locations in the 2020. Box-and-whisker plots show the minimum, maximum, 25th and 75th percentiles, median, and outlier (>2 interquartile ranges from the median) values. The shaded area is the range of the Illinois pH standard of 6.5-9.0 S.U. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each. 39

Figure 8. Temperatures measured continuously by Datasondes deployed for 3-4 day periods during August 21-24 and 24-27, 2020 at 12 locations and continuous data at three locations in the 2020. Box-and-whisker plots show the minimum, maximum, 25th and 75th percentiles, median, and outlier (>2 interquartile ranges from the median) values. The solid and dashed lines are the Ohio EPA maximum and average summer period criteria for similarly sized rivers and streams in the Ohio River basin. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each. 40

Figure 9. Concentrations of mean ammonia-N in the upper Des Plaines River mainstem during June-October 2016-2020. Dashed and solid lines represent IPS derived effect thresholds correlated with ranges of biological quality and as listed in Table 7. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each..... 41

Figure 10. Concentrations of median total phosphorus in the upper Des Plaines River mainstem during June-October 2016-2020. Dashed and solid lines represent IPS derived effect thresholds correlated with ranges of biological quality and as listed in Table 7. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each. 42

Figure 11. Concentrations of median total (open symbols) and dissolved phosphorus (blue symbols) in the upper Des Plaines River mainstem during June-October 2016-2020. Dashed and solid lines represent IPS derived effect thresholds for total P correlated with ranges of biological quality and as listed in Table 7. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each..... 43

Figure 12. Concentrations (mg/L) of median nitrate-N in the upper Des Plaines River mainstem during June-October 2016-2020. Dashed and solid lines represent IPS derived effect thresholds correlated with ranges of biological quality and as listed in Table 10. A key to

sources (arrows and numbers) is in the table above the figure along with flow and loads from each.	44
Figure 13. Concentrations (mg/L) of median total Kjeldahl nitrogen (TKN) in the upper Des Plaines River mainstem during June-October 2016-20. Dashed and solid lines represent IPS derived effect thresholds correlated with ranges of biological quality and as listed in Table 6. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each.	45
Figure 14. Concentrations (mg/L) of median total suspended solids (TSS, upper) in the upper Des Plaines River mainstem during June-October 2016-2020. Dashed and solid lines represent IPS derived effect thresholds correlated with ranges of biological quality and as listed in Table 10. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each.	46
Figure 15. Concentrations (mg/L) of median total chloride in the upper Des Plaines River mainstem during June-October 2016-2020. Dashed and solid lines represent IPS derived effect thresholds correlated with ranges of biological quality and as listed in Table 7. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each.	51
Figure 16. Specific conductance ($\mu\text{S}/\text{cm}$) measured continuously by Datasondes deployed for multiday periods during mid-August at 15 locations in the 2020 study area. Box-and-whisker plots show the minimum, maximum, 25th and 75th percentiles, median, and outlier (>2 interquartile ranges from the median) values. The IPS thresholds for five narrative ratings are shown by solid and dashed lines. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each.	52
Figure 17. Median specific conductance in the upper Des Plaines River mainstem during June-October 2016-20. Dashed and solid lines represent IPS derived effect thresholds correlated with ranges of biological quality and as listed in Table 6. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each.	53
Figure 18. Qualitative Habitat Evaluation Index (QHEI) scores in the upper Des Plaines River mainstem in 2016, 2018, and 2020. The IPS narrative ranges of QHEI scores from excellent to very poor are indicated by solid and dashed lines. A key to sources (arrows and numbers) is in the table above the figure along with flows and loads from each.	55
Figure 19. Illinois macroinvertebrate IBI scores in the upper Des Plaines River mainstem in 2016, 2018, and 2020. IEPA thresholds for determining full support, non-support-fair, and non-support-poor of the General Use for aquatic life are indicated by dashed lines and grey shading. A key to sources (arrows and numbers) is in the table above the figure along with flows and loads from each.	59
Figure 20. Two (2) Round Gobies (<i>Neogobius melanostomus</i>) collected at site 16-1 (RM 71.7) on August 14, 2020. Twenty-one (21) Round Goby individuals were collected at the four downstream most sites during the 2020 survey of the upper Des Plaines River mainstem. 62	
Figure 21. Illinois fish IBI (fIBI) scores for the upper Des Plaines River in 2016, 2018, and 2020. IEPA thresholds for determining full support, non-support-fair, and non-support poor of the	

General Use for aquatic life are indicated by dashed lines and grey shading. A key to sources (arrows and numbers) is in the table above the figure along with flows and loads from each.

..... 63

Figure 22. Modified Index of Well-Being (MIwb) for the upper Des Plaines River in 2016, 2018, and 2020. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each. 64

Figure 23. Area of Degradation (ADV; cross hatched) and Area of Attainment (AAV; open shading) values in the upper reach and remaining lower reach of the upper Des Plaines River in 2016, 2018, and 2020 (upper and middle panels). The miles of full and non-attainment appear in the lower panel..... 67

LIST OF TABLES

Table 1. Aquatic life use attainment status in the 2020 Upper Des Plaines River study area with associated causes and sources of impairment listed for partial and non-supporting sites (see footnotes for fIBI and mIBI use support thresholds); 2018 sources are listed for comparison. The fIBI, MIwb, and mIBI values are color coded in accordance with meeting five narrative classes (key at bottom of the table). IPS restorability scores are provided for non- and partially supporting sites and susceptibility and threat scores are provided for fully supporting sites..... 2

Table 2. E. coli values (cfu/100 ml) for samples collected in the Year 2 Upper Des Plaines River study area during May-October 2015 thru 2018. Yellow shaded values exceed the recommended U.S. EPA (2012) 90-day geometric mean (126 cfu/100 mL) and red shaded values exceeded the maximum STV (410 cfu/100 mL) recreation use criteria..... 7

Table 3. Level IV subregions of the 2016 Upper Des Plaines River watershed study area and their key attributes (from Woods et al. 1995)..... 11

Table 4. Major wastewater treatment facilities that discharge either directly or via tributaries (river miles are indicated) to the 2018 Upper Des Plaines River mainstem (DPW – Dept. of Public Works; NSWRD – North Shore Water Reclamation District; WRF – Water Reclamation Facility; WWTP – Wastewater Treatment Plant). Treatment levels and nutrient information from U.S. EPA Discharge Monitoring Report (DMR) Pollutant Loading Tool (https://cfpub.epa.gov/dmr/facility_detail.cfm)..... 12

Table 5. Locations of sampling sites in the Year 2 Des Plaines River study area in 2020 showing the site ID, river or stream, location, river mile, and what sampling was performed at each (F – fish; MH – multihabitat macroinvertebrate; QHEI – Qualitative Habitat Evaluation Index; Datasonde; Benthic Chlorophyll a, and water chemistry in accordance with Tier 1-4 designation..... 17

Table 6. Summary of the number of water chemistry parameters and samples collected by parameter category in 2020. 19

Table 7. Biological effect thresholds derived from Northeast Illinois streams and rivers for selected water column parameters as part of the NE Illinois IPS development and used to assess results from the Year 4 Des Plaines River study area. The most limiting of the fish or macroinvertebrate assemblages for each parameter are indicated along with thresholds for excellent, good, fair, poor, and very poor biological condition along with FIT score (see Appendix D), sample N, and regional reference values for NE Illinois rivers and streams <350 mi. ² .	32
Table 8. Biological effect thresholds derived from Northeast Illinois streams and rivers for selected sediment chemical parameters as part of the NE Illinois IPS development and used to assess results from the Year 4 Des Plaines River study area. The most limiting of the fish or macroinvertebrate assemblages for each parameter are indicated along with thresholds for excellent, good, fair, poor, and very poor biological condition, FIT score (see Appendix D), and sample N for NE Illinois rivers and streams <350 mi. ² .	33
Table 9. Biological effect thresholds derived from Northeast Illinois streams and rivers for selected habitat and land use variables as part of the NE Illinois IPS development and used to assess results from the Year 4 Des Plaines River study area. The most limiting of the fish or macroinvertebrate assemblages for each variable are indicated along with thresholds for excellent, good, fair, poor, and very poor biological condition along with FIT score (see Appendix D), sample N, and regional reference values for NE Illinois rivers and streams <350 mi. ² .	34
Table 10. Median values for 11 selected chemical/physical water quality parameters and mean ammonia-N at 20 sites in the Year upper Des Plaines River study area in 2020. NE Illinois IPS thresholds are listed at the bottom of the table and the results are color coded accordingly. The difference between total P and ortho P is reported with differences >0.10 yellow highlighted.	35
Table 11. Exceedances of the different parts of the Illinois dissolved oxygen (D.O.) water quality standard among the three continuously operated Datasondes in the upper Des Plaines River during the summer-early fall period of 2020.	36
Table 12. Results of applying a modified Stream Nutrient Assessment Procedure to the 2020 Year 4 study area. Descriptions of how each result reflects the degree of nutrient enrichment effects and which results in an assignment of overall enrichment status are shown at the bottom of the matrix along with the source of the thresholds for each primary (blue shaded), secondary (green shaded), and tertiary (tan shaded) parameter. The weighted SNAP score for each parameter and the total SNAP score for deriving the overall enrichment status are shown adjacent to each site parameter value. Biological sampling sites that lacked continuous D.O. data were not assigned an overall enrichment status, but were included for comparison of the biological attainment status, habitat quality, and nutrient parameters that were available. Sestonic chlorophyll a scores for sites with no sestonic chlorophyll a values were based on adjacent sites.	48
Table 13. QHEI matrix of good and modified habitat attributes for sites in the upper Des Plaines River Year 4 study area during 2020. QHEI scores are shaded in accordance with IPS derived	

ranges; blue – excellent; green – good; yellow – fair; orange – poor; red – very poor. Ratios of poor and good attributes and modified:good ratios are shaded in accordance with the narrative categories at the bottom of the table..... 56

Table 14. The fifteen (15) most abundant macroinvertebrate taxa collected in the upper Des Plaines River mainstem including sites collected, numbers collected, taxa group, functional group, and taxa tolerance assignments..... 58

Table 15. Selected macroinvertebrate assemblage attributes for sites sampled in the Upper Des Plaines Year 4 study area in 2020. Biological index scores selected metrics are shaded by narrative quality as follows: exceptional – blue; good (fully supporting) - green; fair (non-support) - yellow; poor (non-support) – orange; very poor – red (non-support); signatures of toxic and organic enrichment responses are based on Yoder and DeShon (2003). 60

Table 16. The fifteen most abundant species by number (left panel) by weight (right panel) collected in the upper Des Plaines mainstem in 2020. IL and OH tolerance assignments, numbers/weight (kg) collected, and percent collected by each (species with blank tolerance cells are intermediate)..... 61

Table 17. Selected fish assemblage attributes for sites sampled in the Upper Des Plaines Year 4 study area in 2020. Biological index scores selected metrics are shaded by narrative quality as follows: exceptional – blue; good (fully supporting) - green; fair (non-support) - yellow; poor (non-support) – orange; very poor – red (non-support); signatures of toxic and organic enrichment responses are based on Yoder and DeShon (2003). 65

Table 18. Key chemical, physical, and biological response indicators of impairment observed at each site in the Upper Des Plaines River study area in 2020. The causes associated with biological impairments are drawn from analyses of habitat, nutrient effects, chemical IPS and other threshold exceedances, sediment chemical IPS exceedances, and biological response signatures. Causes of impairment are classified as fair, poor, or very poor in accordance with the exceedance of corresponding thresholds. See footnotes for table references and biological, physical, and chemical threshold intervals. IPS restorability score are provided for non- and partially supporting sites and susceptibility and threat scores are provided for fully supporting sites..... 68

ACKNOWLEDGMENTS

Chris O. Yoder, MBI, served as the report editor and project manager. Technical contributions to the report and the analyses were made by Edward T. Rankin, Matthew A. Sarver, Vickie L. Gordon, Martin J. Knapp, and Blair A. Prusha, all of MBI. Database management and data analysis were provided by Edward T. Rankin and Vickie L. Gordon. Field crew leaders were Blair Prusha (macroinvertebrate assemblage), Matthew Sarver (fish assemblage and habitat), and Vickie L. Gordon (Datasonde and Benthic Chlorophyll a). Field sampling assistance was provided by Alex Roller-Knapp, Paul DeRolf, Michael Whitacre, and McKenzie Thompson. Logistical and administrative support at MBI was provided by Allison Boehler, Chelsea Dingess, and Emily Frechette. Chemical analysis was provided by Suburban Labs for samples collected by DRWW and by the University of Washington for benthic chlorophyll a. Overall DRWW project management was originally directed by Beth Adler, DRWW, and Joe Robinson, DRWW Monitoring Committee Chair. Ashley Strelcheck and Mike Prusila, DRWW assumed the project management role and Steve Waters the DRWW Monitoring Committee Chair in 2021 and coordinated a review of the draft and final report. All members of the DRWW Monitoring Committee are acknowledged for their review and edits. We also recognize DRWW for assistance provided with the location of and access to sampling sites.

FOREWORD

What is a Biological and Water Quality Survey?

A biological and water quality survey, or “bioassessment”, is an interdisciplinary monitoring effort coordinated on a waterbody specific or watershed scale. This may involve a relatively simple setting focusing on one or two small streams, one or two principal stressors, and a handful of sampling sites or a much more complex effort including entire watersheds, multiple and overlapping stressors, and tens of sites. The 2020 monitoring rotation included 17 sites on the Upper Des Plaines River mainstem, two sites on North Mill Creek, and a single site on Mill Creek all within Lake County except for a single site on the mainstem located in Cook County. All of these sites were previously sampled in 2016 biological assemblages and habitat and a portion of the mainstem annually since 2015 for water chemistry. The principal focus of the 2020 bioassessment is on the status of the Illinois General Use for aquatic life and recreation.

Scope of the 2020 Biological and Water Quality Assessment

The Midwest Biodiversity Institute (MBI) was contracted by the Des Plaines Watershed Workgroup (DRWW) to develop a biological and water quality monitoring and assessment plan for the Upper Des Plaines River watershed within Lake County, IL. The plan was incorporated into a Quality Assurance Project Plan (QAPP; DRWW 2016) that was submitted to and approved by Illinois EPA. The spatial sampling design consisted of an intensive pollution survey and geometric allocation of sites. This design was employed to fulfill multiple purposes and goals in addition to the determination of the existing status of the biological assemblages and their relationship to chemical, physical, and biological stressors. Targeted sites were positioned upstream and downstream from major discharges, other sources of potential pollution releases and contamination, and major tributaries to provide a “pollution profile” of the major mainstem streams and rivers. Sampling locations in the smaller tributaries were allocated by a geometric progression of drainage area to a “resolution” of 0.5-1.0 square miles. The major program objectives include:

1. Determine the aquatic life status of each sampling location in quantitative terms, i.e., not only if a waterbody is impaired, but the spatial extent and severity of the impairment and the respective departures from established criteria;
2. Determine the proximate stressors that correspond to observed impairments to target management actions to those stressors; and,
3. Screen for any potential issues with use attainability.

To meet these objectives data was collected with methods that provide high-quality results and in conformance with the practices of Illinois EPA (IEPA 2010a,b; 2011a-g; 2014a,b) and Illinois DNR (2010a,b) and under a project QAPP approved by IEPA (DRWW 2016).

Previous biological assessments of the Upper Des Plaines River basin streams and rivers include major surveys by Illinois EPA (IEPA 1988,), Illinois DNR (IDNR; Pescitelli and Widloe 2018; Pescitelli 2016; Pescitelli and Rung 2010a,b; Day 1991; Heidinger 1989; Bertrand 1984; Langbein and Wright 1976; Muench 1968), Illinois Natural History Survey (Bilger et al. 2016; Sherwood et al. 2016), U.S. Geological Survey (Steffeck and Streigl 1989), Shedd Aquarium (Bland and Willink 2015), and others (Slawski et al. 2008). Some of these surveys included the entirety of the Des Plaines River and others focused on the Upper Des Plaines defined as the mainstem and tributaries upstream from the confluence with Salt Creek. Smaller surveys of specific tributaries in Lake Co. have also been conducted, but none were of sufficient scope or coverage to meaningfully compare to the initial watershed assessment in 2016 (MBI 2017), the Year 1 watershed bioassessment of the Indian, Buffalo, or Aptakisic Creek subwatersheds (MBI 2018), or the Year 3 watershed assessment of the Mill Creek, Bull Creek, and Upper Des Plaines River Tributary Subwatersheds (MBI 2021).

The recent basin-wide fish surveys by IDNR included only a single site located on Indian Creek. Other fish surveys include two sites on Seavey Drainage Ditch (pre- and post-dam removal 2008, 2010), a qualitative fish survey in Seavey Ditch and Indian Creek in June 2016 (Bland et al. 2016) and a more recent and comprehensive survey of fish, macroinvertebrates, and mussels in streams potentially impacted by the State Route 53 extension northward through Lake Co. in 2014 and 2015 (Sherwood et al. 2016; Bilger et al. 2016; Douglas et al. 2016). This included 3 sites in the Buffalo Creek subwatershed and 7 sites in the Indian Creek subwatershed sampled for fish and 4 of these 10 sites sampled for macroinvertebrates.

The 2020 Year 4 assessment followed the Year 2 2018 mainstem assessment and continued to utilize the analyses and outputs of the Northeastern Illinois Integrated Prioritization System (NE IL IPS; MBI 2020a). Biological effect thresholds for five biological condition categories (i.e., excellent, good, fair, poor, and very poor) were developed for 87 chemical water quality, sediment chemistry, and habitat attributes that are more regionally relevant than what has been used previously. For nutrients, this includes not only more refined thresholds for nutrient parameters but a combined assessment that assembles indicators and parameters of the direct and indirect effects of nutrients. The IPS yields a Restorability factor for impaired sites, reaches, and watersheds and a Threat/Susceptibility factor for attaining sites. In combination with better stressor thresholds and across five condition categories this has provided more certainty of the assignment of causes and sources of impairment and threats.

EXECUTIVE SUMMARY

Summary of Findings

Aquatic Life Condition Assessment

The primary indicators of the status of the Illinois General Use for aquatic life are the Illinois fish and macroinvertebrate Indices of Biotic Integrity and generally following the guidance in the 2018 Integrated Report (IEPA 2018) with certain exceptions. The status of aquatic life is reported here in an attainment table (Table 1) and expressed as full, partial, or non-support and based on the most limiting of either the fish or macroinvertebrate results. Non-support is further subdivided into non-support fair and non-support poor; the partial support category was added to clarify instances where only one of the two assemblages attains the General Use support fish or macroinvertebrate threshold. The 2020 results showed a single site in full attainment of the General Use for aquatic life, down from five (5) sites in full attainment in 2018 (MBI 2020b). The fish assemblage was limiting as the macroinvertebrate IBI met its criteria at all except two (2) sites in the effluent affected portion of the upper mainstem. The 2020 fIBI scores declined at the formerly attaining sites by anywhere from 2.0 to 7.5 fIBI units with two sites missing by 1.5 fIBI units. The introduction of large volumes of treated municipal wastewater continues to benefit the Des Plaines River and aides in offsetting detrimental impacts that are exported downstream from the modified upper reach of the mainstem. Even with the lower fIBI scores in 2020, the longitudinal pattern was the same – consistent incremental improvement downstream from the Wetland Research riffle and seemingly independent of the entry of large volumes of treated wastewater. This and the accumulation of more poor and very poor exceedances of IPS and other thresholds in the upper modified reach are primarily from nonpoint sources being exacerbated by the habitat and hydrological modifications in the upper watershed as the major limiting sources to aquatic life.

Only a single site (16-2) was in full attainment of the General Use for aquatic life in 2020 down from five sites in 2018 all in the effluent dominated reach of the study area (Table 1). Partial attainment was observed in the reach between site 13-1 (RM 94.2) and site 16-3 (RM 76.70) with the exception of site 16-8 (RM 82.90) which was non-fair. Each of these sites were limited by non-attainment of the fIBI biocriterion with most scores marginally lower than in 2018. The sites immediately upstream and downstream from the Libertyville and Mundelein WWTPs missed full attainment by only 1.5 units. The discovery of Round Goby at the four (4) downstream most sites also adds an unknown factor for the aquatic assemblages¹. With no barriers until the Wetland Research riffle the species will likely move farther upstream, possibly having deleterious effects on the already marginal fish assemblage. The biological results downstream from the entry of treated wastewater at site 13-3 were better both in terms of AQLU status and the fIBI and mIBI scores than at the five upstream most sites that were in non-fair and non-poor attainment status and with four (4) of five (5) fIBI scores in the poor range.

¹ See <https://nas.er.usgs.gov/queries/factsheet.aspx?SpeciesID=713> for potential adverse impacts to native species.

Table 1. Aquatic life use attainment status in the 2020 Upper Des Plaines River study area with associated causes and sources of impairment listed for partial and non-supporting sites (see footnotes for fIBI and mIBI use support thresholds); 2018 sources are listed for comparison. The fIBI, Mlwb, and mIBI values are color coded in accordance with meeting five narrative classes (key at bottom of the table). IPS restorability scores are provided for non- and partially supporting sites and susceptibility and threat scores are provided for fully supporting sites.

Causes and Sources of Non-attainment¹

Causes and sources were determined for each impaired site and included categorical or parameter level associations and their sources (if known). With the recent availability of more comprehensive and regionally relevant analyses of stressors in the Northeast Illinois via the Integrated Prioritization System (NE IL IPS; MBI 2020a) assigning causes could be weighted by exceedances of very poor, poor, and fair IPS threshold values. This approach still involves using a line of evidence approach where chemical and physical threshold exceedances generated by the NE IL IPS within a causal category (or for a parameter) is better related to a biological impairment. This goes well beyond the association of a coincidental exceedance of a criterion or other threshold with a biological impairment. Knowing about relationships that are supported by prior empirical observations in other studies and our own experiences continues to boost the confidence in causal assignments. This process varies from that used by IEPA in that additional and regionally developed effect thresholds were used to derive causes beyond those used by IEPA (2022).

Nineteen (19) causes across four (4) major categories and six (6) major sources were identified for the upper Des Plaines River mainstem in 2020 (Figure 1). Of the 19 causes, six (6) were habitat related, nine (9) were chemical, three (3) D.O., and two (2) land use. The proportion of causes was assessed based on the number of observations and weighted observations (Figure 1), the latter being based on the severity of the expression of the specific stressors within a causal category. A higher weighting was assigned based on the narrative rating of an exceedance with 5 for very poor, 3 for poor, and 1 for fair. Thirteen (13) causes across seven (7) major categories and five (5) source categories were identified for the upper Des Plaines River mainstem in 2018 (MBI 2020b). Multiple very poor and poor causes were restricted to the uppermost five (5) sites in 2020, but one or two exceedances occurred sporadically at all except the downstream most site in 2020. In 2018 seven (7) sites including and downstream from site 13-3 at U.S. Rt. 41 had one or more causes with poor threshold exceedances.

Macro Habitat Related (39.5%) was the most pervasive cause followed closely by Organic/Nutrient Enrichment (36.5%) based on the weighted frequency of each. D.O. related issues at 13.8% comprised about one-third of the observations of either Macro Habitat Related or Organic/Nutrient Enrichment issues with Urban Related causes at 10.2%. There were no Toxics Related causes observed in 2020 which is likely related to the omission of sediment chemistry in 2020. The Macrohabitat Related, Organic/Nutrient Enrichment, and D.O. Related had the only poor and very poor values that were primarily observed in the 10 mile long modified upper reach upstream from the Wetland Research Riffle with observations of very poor and poor Organic/Nutrient Enrichment issues observed immediately downstream of the Wetland Research Riffle. Very poor and poor nutrient exceedances occurred sporadically in the middle and lower reaches of the mainstem. Very poor and poor ammonia-N levels occurred downstream from the Libertyville and Mundelein WTPs, but none of these values would have exceeded the Illinois WQC for ammonia-N. Elevated levels of Nitrate-N and total P in the poor and most frequently in the fair range were primarily observed in the effluent influenced reaches of the middle and lower mainstem. Urban related causes exceeding mostly fair thresholds occurred mostly in the middle and lower mainstem, but poor exceedances of the

Major Causes (Unweighted %) Associated with Aquatic Life Impairments: 2020

Major Causes (Weighted %) Associated with Aquatic Life Impairments: 2020

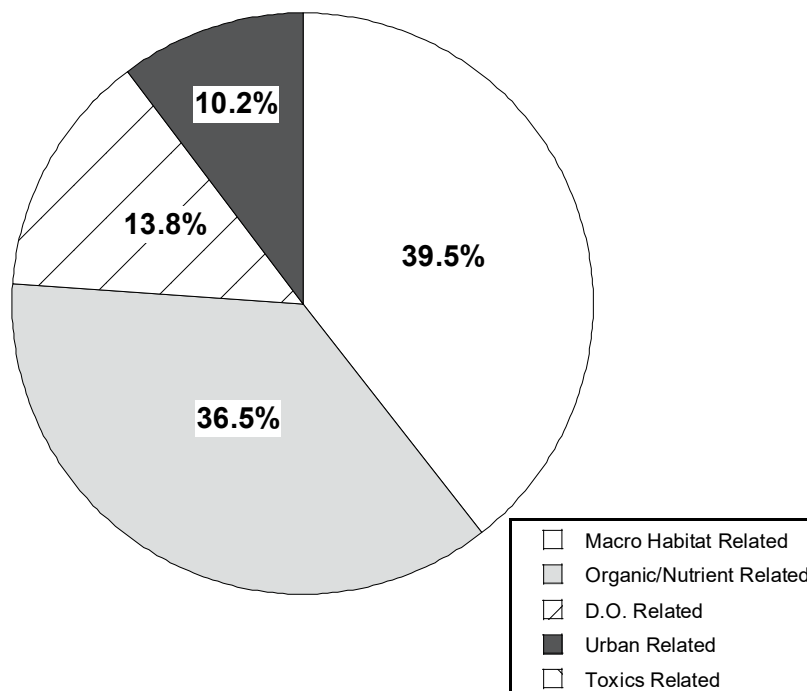

Figure 1. Major categorical causal groupings associated with aquatic life impairments in the upper Des Plaines River mainstem in 2020 based on the number of observations (upper) and weighted observations (lower), the latter based on the narrative rating of IPS threshold exceedances (very poor = 5, poor = 3, and fair = 1).

Impervious Cover-30 meter buffer occurred at the two upstream most sites. These results are similar to the 2018 results although the 2020 causal categories were further refined in 2020.

IPS Restorability, Susceptibility, and Threat Results

The Northeast Illinois Integrated Prioritization System (IPS; MBI 2020a,b)) was used to calculate the Restorability scores for non-attaining and partially attaining sites and Susceptibility and Threat scores for the single fully attaining sites. Fifteen non-supporting and partially supporting sites had Restorability scores and one (1) fully supporting site had Susceptibility and Threat score calculated. In terms of Restorability 10 of the 15 non and partially attaining mainstem sites had Restorability scores ranked as high. The high rankings mean that the likelihood of reaching full attainment is plausible and likely accomplished without major physical restoration interventions. The remaining five (5) impaired mainstem sites ranked as moderate. None of these sites had any very poor causes assigned and three were impacted by hydromodifications located immediately upstream. The highest ranked sites were located downstream of the Wetland Research Riffle and the reach receiving the majority of the municipal wastewater that enters the mainstem. Two (2) sites in the lower watershed (16-3 and 16-8) missed a high Restorability ranking by only 3.6 and 1.8 points respectively. The other four (4) moderate ranked sites occurred in the upper mainstem that have been subject to more severe hydromodifications including legacy channelization with little or no recovery and flow alteration. These sites also exhibited multiple poor and very poor causes of impairment including low D.O., excessive diel D.O. swings, elevated turbidity, siltation, and a predominance of modified QHEI attributes. Addressing these impairments would require structurally oriented restoration actions to address the modified habitat (i.e., reduce or eliminate the modified habitat attributes) and altered flow conditions which would be a significant undertaking for a river channel of that size.

For the single fully supporting site, Susceptibility and Threat scores were applied. In terms of the narrative assignments being used at present (see Table 1, bottom), the Susceptibility ranking was low and the Threat ranking was also low. The Threat ranking for site 16-2 of 60 barely meets the threshold for a low score. Several factors influenced the Threat ranking and the ability of the assemblages to meet full use attainment status. Elevated levels of ammonia-N and nitrate-N emanated from the general vicinity of Libertyville downstream to just above the DesPlaines River WRF. Habitat quality limitations including a high number of poor attributes and only a moderate number of good attributes yielded a fair ratio of modified to good habitat attributes. The full attainment at site 16-2 in 2020 indicates that the impacts from upstream sources can be mitigated through the introduction of properly treated wastewater despite some habitat limitations. The reach with the four (4) previously attaining sites in 2018 that were in partial attainment in 2020 had very poor concentrations of ammonia-N and elevated nitrate-N levels in 2020. Habitat is not limiting at any of these sites.

Synthesis of Results

The influx of large volumes of treated municipal wastewater continues to offset the detrimental impacts of the upstream, modified section. Better habitat and flow conditions in the lower

watershed provide improved habitat conditions for aquatic assemblages, where nine (9) of the 11 sites downstream of the Wetland Research Riffle at least partially attaining the General Use criterion, and 16-2 (RM 75.4) fully attaining. The Susceptibility Score and the IPS Threat Score were low for 16-2. The majority of sites located downstream of the Wetland Research Riffle that were in partial attainment possess high Restorability rankings. Sites 16-7, 16-6, 13-16, and 13-1 previously fully attained in 2018, however, departed the General Use for the fIBI by fewer than 6 points. These four (4) sites have high Restorability rankings. The site below the Wetland Research Riffle and the Waukegan WRF (13-3) was in non-attainment (Fair) with fIBI and mIBI missing attainment by 9 and 8.2 points respectively. Further downstream an incremental improvement in the mIBI was observed at 13-2, however, the fIBI did not significantly differ. Partial attainment was observed downstream of the Gurnee WRF, Libertyville and Mundelein WRFs, and New Century Town WRF with the fIBI failing to meet the General Use biocriterion. The upper watershed sites generally had the lowest mIBI and fIBI as well as the lowest Restorability rankings in the mainstem. The AQLU status did not exceed low-fair at any site and the Restorability rankings were moderate at all sites. The historic channelization and wetland nature of the upper watershed provide limitations to the attainment of the General Use criteria for both the macroinvertebrate and fish assemblages. Despite the observed declines in the overall quality of both assemblages in the lower watershed, and if wastewater effluent quality is improved upon, then the full attainment observed can be expanded from the five (5) locations.

Recreational Use Assessment

Levels of fecal bacteria in the form of *Escherichia coli* (*E. coli*) cfu²/100 mL were used to assess the status of recreation in and on the water. The IEPA General Use criteria are expressed as counts of fecal coliform bacteria, which were not measured here, hence the U.S. EPA national criteria for *E. coli* were used instead. The U.S. EPA *E. coli* criteria are expressed in terms of a 90-day geometric mean and a statistical threshold value (STV) which is the 90th percentile of the data distribution that is not be exceeded by more than 10 percent of the samples. Given the small sample size limitations of this survey, mean values of 2-3 samples were used as an approximation of the 90-day geometric mean and maximum values as the STV. The U.S. EPA recommended 90-day geometric mean criteria value is 126 cfu/100 ml and the STV criteria value is 410 cfu/100 ml (U.S. EPA 2012).

E. coli results for the Des Plaines River mainstem at 17 locations were available from 2020, at 16 locations in 2018 and 2019, and at 12 locations in 2015, 2016, and 2017 each (Table 2). The frequency of exceedances of the U.S. EPA recommended geometric mean and STV criteria have generally declined since 2015, however, exceedances in the geometric mean or maximum STV was observed at all sites in 2019. A majority of the sites had exceedances of both. The high number of exceedances is attributed to the higher levels of precipitation in 2019 that caused increased runoff. Only 16-7 (RM 84.6) did not exceed the maximum STV and only 16-5 (RM 83.6) did not exceed the geometric mean. The frequency of exceedances declined in 2020 to levels equivalent to observations in 2018. Among the 17 sites sampled for *E. coli* in 2020, four (4) had maximum values that exceed the STV and four (4) had exceedances of the geometric mean, including two (2) having exceedances of both criteria (Table 2). The dual exceedances at

Table 2. *E. coli* values (cfu/100 ml) for samples collected in the Year 2 Upper Des Plaines River study area during May-October 2015 thru 2018. Yellow shaded values exceed the recommended U.S. EPA (2012) 90-day geometric mean (126 cfu/100 mL) and red shaded values exceeded the maximum STV (410 cfu/100 mL) recreation use criteria.

13-18 (RM 99.72) are attributed to nonpoint runoff as are exceedances at 13-1 (RM 94.2) despite being located 1.2 miles downstream of the Gurnee WRF outfall which has consistently low cfu/100 mL counts. The exceedance of the geometric mean at 16-7 (RM 84.6) also occurred at the site in 2018, which is located 0.2 miles downstream of the Mundelein and Libertyville WWTPs. Years with lower observed flows saw exceedances of *E. coli* from point sources, while in years with higher flows nonpoint sources exacerbate increased concentrations (MBI 2020b). The low frequency of samples in a given year continues to limit the diagnostic value of the data hence a more intensive study would need to be undertaken to firm up the recreational use status and to better pinpoint sources of *E. coli*.

Biological and Water Quality Assessment of the Upper Des Plaines River: Year 4 Rotation 2020

Study Area Description

Lake County is comprised of 53 individual communities and 18 townships with a total area of 1368 square miles of which a significant fraction are waterbodies comprised of lakes, wetlands, rivers, and streams in the Upper Des Plaines River basin. According to the 2018 American Community Survey estimate, there are 700,832 residents in Lake County and 263,360 housing units, making it the third most populated county in Illinois (USCB, 2020). The 2020 study area covers roughly 135 square miles of the upper Des Plaines River watershed including Mill Creek, North Mill Creek, and the mainstem of the Des Plaines River. North Mill Creek originates in Wisconsin near Bristol and flows 17 miles to its confluence with Mill Creek near Lindenhurst, IL. Mill Creek originates near the Village of Grayslake, IL, and flows 18.5 miles to its confluence with the Des Plaines River near Wadsworth, IL. The Des Plaines River originates in Wisconsin near Racine in Kenosha Co. north of where it enters Illinois in Lake County. The Des Plaines River flows due south for 110 miles joining the Kankakee River to form the Illinois River. The total watershed area is approximately 2110 square miles of which 1231 are in Illinois (Healy 1979). The watershed in Lake Co. is “trellised” meaning it is narrow relative to the length of the mainstem thus the tributaries are of comparatively shorter lengths with comparatively small drainage areas.

General Landscape Setting

The study area occurs in the Kettle Moraine subregion of the Southeastern Wisconsin Till Plains Level III ecoregion and the Valparaiso-Wheaton Morainal Complex subregion of the Central Corn Belt Plains Level III ecoregion (Table 3; Woods et al. 2006). The Kettle Moraine subregion occupies the majority of the study area to the west and northwest of the mainstem. It is characterized by poorly drained, hilly to hummocky morainal areas that include conspicuous glacial landforms, numerous lakes, and wetlands including bogs, fens, and marshes. Drainage networks are less integrated and more poorly developed than on the older till and outwash plains of the adjacent Rock River Drift Plain subregion. Lakes are typically larger and more concentrated than to the south in the Valparaiso Morainal Complex subregion and much more common than in other neighboring subecoregions. Soils are largely derived from thick late-Wisconsinan glacial drift and loess deposits, where they occur, are thin. Alfisols are common, but Mollisols and Histosols also occur. Overall, organic soils are more extensive than elsewhere in Illinois, and Mollisols are less common than in subregions to the west. In the early 1800s moraines were covered by savanna, prairie, and forest (oak-hickory) with depressions containing wetlands. Landscape alterations in the 1900s reduced the tracts of forest and nonforested wetlands replacing them with urban and suburban development. However, wooded areas, lakes, and wetlands are still common, especially in the extensive forest preserves.

Table 3. Level IV subregions of the 2016 Upper Des Plaines River watershed study area and their key attributes (from Woods et al. 1995).

Level IV Subregion	Physiography	Geology	Soils	Potential Natural Vegetation	Land Use/Land Cover
Kettle Moraine (53b)	Glaciated, hummocky to hilly area with steeply sloping moraines, outwash plains, closed depressions, mounds, level areas, and many wetlands and natural lakes.	Wisconsinan-age glacial till, outwash gravels, and thin loess (<20"). Silurian & Ordovician dolomite, limestone, and shale bedrock.	Mostly Alfisols (Hapludalfs, Epiaqualfs); also, Mollisols (Argiudolls, Endoaqualfs), Histosols.	Oak-hickory forest, oak savanna, & bluestem prairie occur on moraines. Wetlands (bogs, fens, seeps, sedge meadows, marshes) were common.	Forest, pastureland, & wetland. Home sites common on moraines and lakes.
Chiwaukee Prairie (54e)	Lake and till plains with beaches, well-developed sand dunes, low beach ridges, swales, and bluffs	Quaternary nearshore lake deposits, beach deposits, glacial till, thin loess, alluvium, outwash deposits, and colluvium.	Alfisols (Hapludalfs, Endoaqualfs)	Bluestem prairie and oak savanna. Tall-grass prairies, scrub oak forests, sand prairies, sand savannas, fens, and marshes.	Cropland, urban and industrial development. Some forested areas.

The Valparaiso-Wheaton Morainal Complex subregion is a hilly, hummocky to rolling area containing moraines, kames, eskers, and outwash plains with numerous small lakes and marshes. Soils are largely derived from thick, late-Wisconsinan glacial drift and loess deposits, where they occur are thin. Alfisols are common and Mollisols also occur, but are less common than in neighboring subregions. In the early 1800s, prairie and forest (oak-hickory) dominated the moraines with swamp white oak forests and marshes occurring in poorly drained areas. Prairie covered slightly more than half of this subregion. Subsequent fire suppression has reduced the number of prairie openings, thereby increasing forest density. Today, pastureland is common, and urban and suburban development is increasing. However, wooded areas, lakes, and wetlands are still common, especially in the extensive County owned forest preserves. Land uses are varied and include residential (26.3%), public/private open space (19.4%), agricultural (12.2%), transportation (10.6%), forest/grassland (9.3%), water (7.0%), wetlands (5.4%), and the remainder comprised of six additional land use types (Lake Co. Local Planning Committee 2012).

Major Point Sources

Significant point sources of pollution were inventoried to understand the extent of the pollution impact and for the intensive pollution survey design. There are a total of 18 wastewater treatment plants (WWTP) in the 2020 study area. Eight (8) are major discharges (Table 4) which comprise 80 million gallons per day (MGD; average annual flows) of treated

wastewater. The North Shore Water Reclamation District Gurnee (NSWRD; 23.6 MGD), NSWRD Waukegan (22.0 MGD), and Lake Co. Dept. of Public Works (LCDPW) Des Plaines River WWTPs (16.0 MGD). The 2020 (Year 4) study area includes seven (7) of the eight (8) major discharges in upper DesPlaines River watershed. All except one of these facilities have advanced treatment for oxygen demanding wastes (BOD), ammonia-N ($\text{NH}_3\text{-N}$), and suspended solids (TSS). The Mundelein WWTP is the only secondary treatment facility remaining in the Year 4 study area. Six (6) facilities have phosphorus removal technology and all seven (7) facilities monitor for N and P (MBI 2017).

Table 4. Major wastewater treatment facilities that discharge either directly or via tributaries (river miles are indicated) to the 2018 Upper Des Plaines River mainstem (DPW – Dept. of Public Works; NSWRD – North Shore Water Reclamation District; WRF – Water Reclamation Facility; WWTP – Wastewater Treatment Plant). Treatment levels and nutrient information from U.S. EPA Discharge Monitoring Report (DMR) Pollutant Loading Tool (https://cfpub.epa.gov/dmr/facility_detail.cfm).

¹ Design average flow from NPDES fact sheet; ² AWT – Advanced Wastewater Treatment – generally 10-20 mg/L CBOD5, 1.5-3.0 $\text{NH}_3\text{-N}$; 12-24 mg/L TSS; Secondary – generally 30 mg/L CBOD5/TSS, and no $\text{NH}_3\text{-N}$ removal; ³ M – nutrient (N and P) monitoring only; P – 1.0 mg/L limitation.

NPDES Permit Special Conditions

All of the major permitted WWTPs are subject to Special Conditions related to the discharge of nutrients, but not all have final language. The first special condition states:

“The Permittee shall, within twelve (12) months of the permit effective date, prepare and submit to the Agency a feasibility study that identifies the method, timeframe, and costs of reducing phosphorus levels in its discharge to a level meeting a potential future effluent standard of 0.5 and 0.1 mg/L. The study shall evaluate the costs of the application of these limits on a monthly, seasonal, and annual average basis.”

The second special condition states:

The Agency has determined that the Permittee's treatment plant effluent is located upstream of a waterbody or stream segment that has been determined to have a phosphorus related impairment. This determination was made upon reviewing available

information concerning the characteristics of the relevant waterbody/segment and the relevant facility (such as quantity of discharge flow and nutrient load relative to the stream flow).

A phosphorus related impairment means that the downstream waterbody or segment is listed by the Agency as impaired due to dissolved oxygen and/or offensive condition (algae and/or aquatic plant growth) impairments that is related to excessive phosphorus levels.

The Permittee shall develop, or be a part of a watershed group that develops, a Nutrient Assessment Reduction Plan (NARP) that will meet the following requirements:

- A. The NARP shall be developed and submitted to the Agency by December 31, 2023. This requirement can be accomplished by the Permittee, by participation in an existing watershed group or by creating a new group. The NARP shall be supported by data and sound scientific rationale.*
- B. The Permittee shall cooperate with and work with other stakeholders in the watershed to determine the most cost-effective means to address the phosphorus related impairment. If other stakeholders in the watershed will not cooperate in developing the NARP, the Permittee shall develop its own NARP for submittal to the Agency to comply with this condition.*
- C. In determining the target levels of various parameters necessary to address the phosphorus related impairment, the NARP shall either utilize the recommendations by the Nutrient Science Advisory Committee or develop its own watershed-specific target levels.*
- D. The NARP shall identify phosphorus input reductions by point source discharges and non-point source discharges in addition to other measures necessary to remove phosphorus related impairments in the watershed. The NARP may determine, based on an assessment of relevant data, that the watershed does not have an impairment related to phosphorus, in which case phosphorus input reductions or other measures would not be necessary. Alternatively, the NARP could determine that phosphorus input reductions from point sources are not necessary, or that phosphorus input reductions from both point and nonpoint sources are necessary, or that phosphorus input reductions are not necessary and that other measures, besides phosphorus input reductions, are necessary.*
- E. The NARP shall include a schedule for the implementation of the phosphorus input reductions by point sources, non-point sources and other measures necessary to remove phosphorus related impairments. The NARP schedule shall be implemented as soon as possible and shall identify specific timelines applicable to the Permittee.*

- F. *The NARP can include provisions for water quality trading to address the phosphorus related impairments in the watershed. Phosphorus nutrient trading cannot result in violations of water quality standards or applicable antidegradation requirements.*
- G. *The Permittee shall request modification of the permit within 90 days after the NARP has been completed to include necessary phosphorus input reductions identified within the NARP. The Agency will modify the NPDES permit, if necessary.*
- H. *If the Permittee does not develop or assist in developing the NARP, and such a NARP is developed for the watershed, the Permittee will become subject to effluent limitations necessary to address the phosphorus related impairments- The Agency shall calculate these effluent limits by using the NARP and any applicable data. If no NARP has been developed, the effluent limits shall be determined for the Permittee on a case-by-case basis, so as to ensure that the Permittee's discharge will not cause or contribute to violations of the dissolved oxygen or narrative water quality standards.*

In addition, all of the WWTPs that are members of the DRWW are subject to additional special conditions in their respective NPDES permits as follows:

“The Permittee shall conduct monthly water quality sampling in the receiving stream both upstream and downstream of the NPDES outfall for the following parameters: dissolved phosphorus, total phosphorus, total organic carbon, chlorophyll a, dissolved oxygen, total ammonia nitrogen, nitrate/nitrite, total Kjeldahl nitrogen, pH, total suspended solids, volatile suspended solids, and temperature. The results shall be submitted to the Agency by March 31 of each year. The Permittee may work cooperatively with the DRWW to conduct monitoring and prepare a single annual monitoring report that is common among DRWW permittees.”

Nutrient Assessment Reduction Plan (NARP)

The State of Illinois developed the Illinois Nutrient Loss Reduction Strategy (NLRs; State of Illinois 2018) to deal with the enrichment of Illinois surface waters by primary nutrients (N and P). As part of the NLRs Illinois EPA developed a process termed the Nutrient Assessment Reduction Plan (NARP) which is to be developed for major wastewater treatment facilities by December 31, 2023. All of the major WWTPs that are members of the DRWW have initiated planning for meeting the NARP requirements. Depending on the findings of the DRWW NARP process additional controls on discharges of N and P could be forthcoming.

Nonpoint Sources

Nonpoint sources in the 2020 study area included a mix of agricultural and urban sources, the latter of varying intensities ranging from light suburban to heavy urban and industrial land uses. These have been extensively classified and delineated by the Lake Co. SMC. Hydromodification of stream and river flows and habitat also occurs with the former being influenced by land uses and the latter mostly in the form of legacy channelization and riparian encroachment by agriculture and urban and suburban development. The influence of legacy hydromodification is especially evident in the upper mainstem.

Sampling Sites Selection and Locations

A Monitoring Strategy for the Des Plaines River Watershed was developed by the Monitoring Committee of the Des Plaines River Watershed Workgroup in 2015 (DRWW 2016). The spatial allocation of sites was established by the DRWW for water sampling in 2015 and this was used as the core for the initial allocation of additional biological and habitat sites. The 2020 survey of the Des Plaines River mainstem is the initial sampling of the mainstem Des Plaines River outside of the yearly rotation. The 2020 site locations are a continuation of previous surveys.

Spatial Survey Design

MBI developed a combined intensive pollution survey and geometric allocation of sites for the sampling of fish, macroinvertebrates, and habitat in 2016 (MBI 2017). This consisted of deriving progressive geometric panels of drainage area and assigning sampling sites where these occurred throughout the Upper Des Plaines watershed. Adding targeted sites to fill gaps in the longitudinal continuum left by the DRWW tiered design to fulfill a pollution survey design for the mainstem and major tributaries resulted in a total of 70 sites. Each sampling site was assigned a unique DRWW numeric site code, a river mile, and UTM coordinates by individual river or stream.

The 2020 study area included 20 sites total including 17 on the mainstem Des Plaines River, two (2) sites on North Mill Creek, and a single (1) site on Mill Creek (Figure 2). All sites except upstream of the wetland riffle (13-19) were sampled for habitat, fish, and macroinvertebrates, and meter-read water quality at a minimum. Macroinvertebrates were not collected at 13-19 due to water being too deep to sample. Twelve (12) sites were sampled with YSI Datasonde recorders continuously with one-half deployed for consecutive one-week periods during August 2020. Benthic chlorophyll-a samples were collected during the same week of deployment at the same sites in which Datasondes were deployed. DRWW grab water samples in 2020 were collected in accordance with designations as Tier 1-3, for which specific analytes varied (Table 5). No water samples were collected at Tier 4 sites, only the four (4) parameters were measured with a handheld water quality meter.

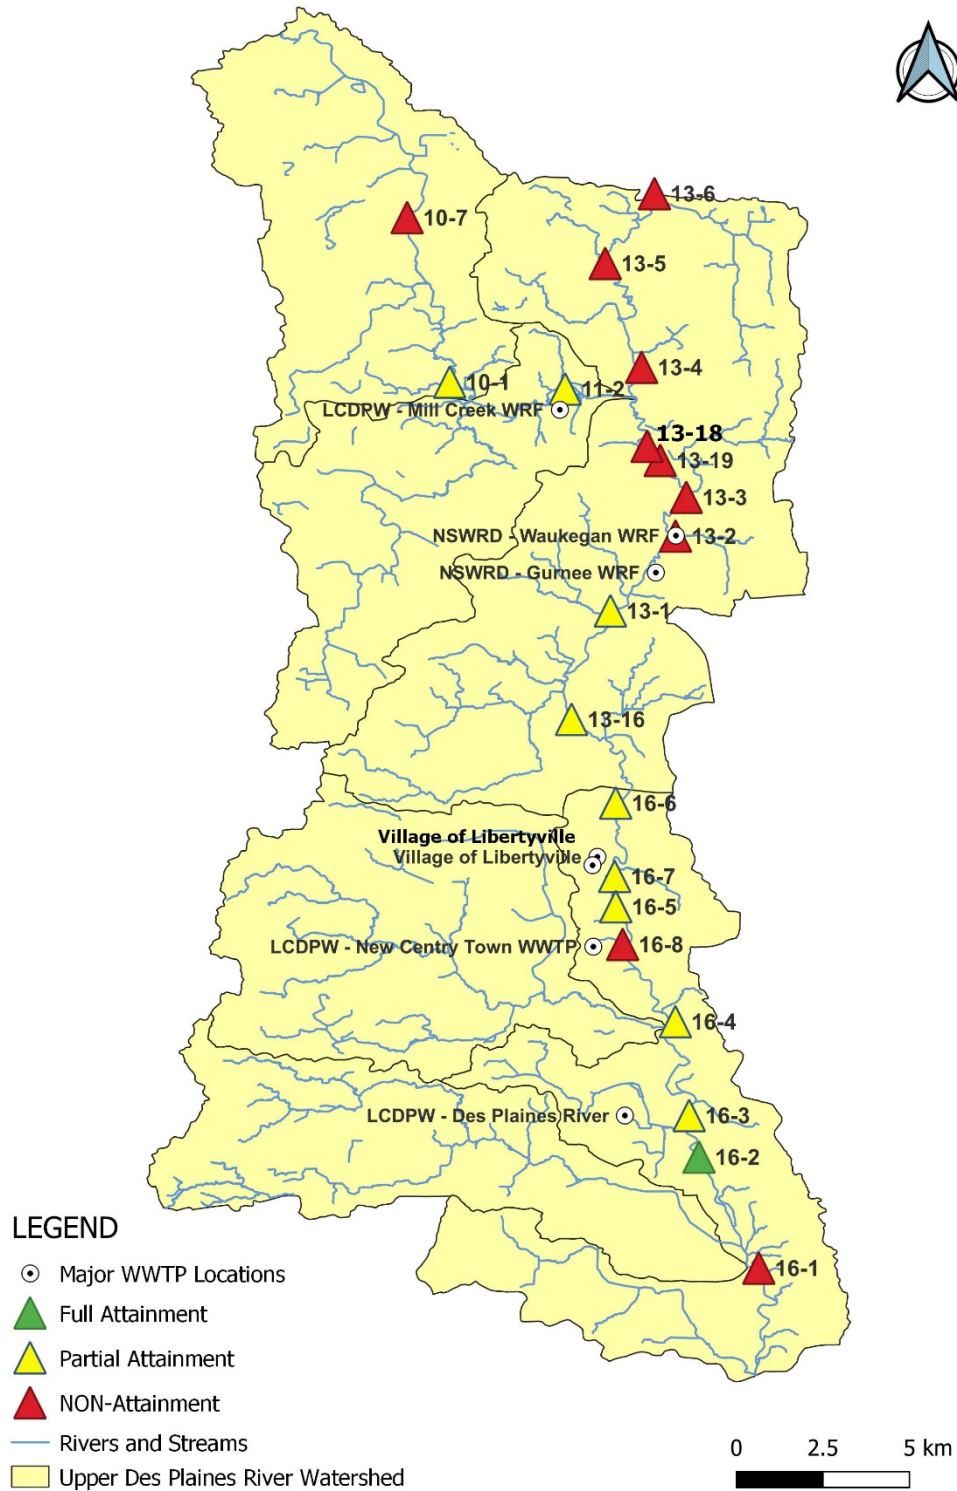

Figure 2. Location of biological, chemical, and habitat sampling sites in the DRWW study area in 2020. Site codes correspond to the sites listed in Table 5.

Table 5. Locations of sampling sites in the Year 2 Des Plaines River study area in 2020 showing the site ID, river or stream, location, river mile, and what sampling was performed at each (F – fish; MH – multihabitat macroinvertebrate; QHEI – Qualitative Habitat Evaluation Index; Datasonde; Benthic Chlorophyll a, and water chemistry in accordance with Tier 1-4 designation.

METHODS

All methods followed Illinois EPA and DNR procedures, except as modified to meet the needs of the DRWW, but with the goal of providing comparable data to evaluate aquatic life and recreational use attainment. This includes fish, macroinvertebrates, habitat, bacteria, chemical parameters (water), continuous data for selected parameters, and benthic chlorophyll a. Recreational use attainment was evaluated with *Escherichia coli* and using the U.S. EPA national criteria since none were available from Illinois EPA.

Chemical/Physical Water Quality – Methods

Water Column Sampling

The specific methods of data collection followed Illinois EPA (2012a) and chemical laboratory analyses were provided by Suburban Labs. The chemical/physical parameter categories (demand, nutrients, metals, and organics) and the frequency of sample collection are summarized in DRWW (2016, 2018). DRWW assigned ties to the sampling sites as follows:

- **Tier 1:** Nine (9) sites located in the Des Plaines River mainstem were sampled monthly for water May through September, and November and March (seven times per year) for all demand, nutrient, and bacteria parameters.
- **Tier 2:** Three (3) sites (2 Des Plaines River, 1 Mill Creek) were sampled monthly from May through September, and in November and March (seven times per year) for the majority of demand, nutrient, and bacteria parameters.
- **Tier 3:** Two (2) sites (1 Des Plaines River, 1 North Mill Creek) were sampled from May through September, and in November and March (seven times per year) for the majority of demand, nutrient, and bacteria parameters.
- **Tier 4:** Six (6) sites (5 Des Plaines River, 1 North Mill Creek) were not sampled for water chemistry. These sites were sampled with a water quality meter during each fish sampling event.

Nutrient Effects Assessment Procedure

The 2020 assessment of the effects from nutrient enrichment was modeled after the Stream Nutrient Assessment Procedure (SNAP) and the large rivers nutrient assessment both developed by Ohio EPA (Ohio EPA 2015b; Miltner 2018). Each includes consideration of the width of the diel variation in continuously measured D.O. and the biomass of chlorophyll a in benthic and sestonic algae in addition to the concentrations of total phosphorus and dissolved inorganic nitrogen (nitrates + nitrites). Other nutrient related parameters such as total suspended solids and total Kjeldahl nitrogen (TKN) were included when they were collected at one of the 13 Datasonde and benthic chlorophyll-a locations (Table 6). Datasondes were deployed by MBI for 4-5 day periods during times of low streamflow and elevated summer ambient temperatures (YSI 2012, 2017). DRWW operated three continuous monitoring locations starting in June 2020 and the corresponding data was also used in the SNAP

assessment. Together these results were used to determine five states of nutrient enrichment, not nutrients excellent, not nutrients good, possibly nutrients, enriched by nutrients, and highly enriched by nutrients, via a weighted scoring process. That process assigned weighted scores to each variable in accordance with the narrative (excellent, good, fair, poor, and very poor) assessment of each including the fish and macroinvertebrate IBI scores which, along with the diel D.O. swing, and chlorophyll a benthic biomass and sestonic concentrations comprise the highest weighted primary variables. The QHEI score, total P, and maximum D.O. were weighted less as secondary parameters, with nitrate-N, minimum D.O., TSS, and TKN weighted the least as tertiary parameters. The sum of parameter scores were normalized to a 0-100 scale for each site with adequate data with lower scores indicating greater effects of nutrient enrichment.

Table 6. Summary of the number of water chemistry parameters and samples collected by parameter category in 2020.

Parameters/Category	Water	
	Parameters	Samples
All	18	4915
<i>E. coli</i>	1	213
Field pH & Temperature	2	641
Demand ¹	1	37
Nutrients ²	7	1870
Ionic Strength ³	4	1373
Suspended Materials ⁴	1	355
Metals	2	426
Organic Compounds	0	0
Other (Cyanide)	0	0
¹ Includes dissolved oxygen and turbidity ² Includes total ammonia, total phosphorus, total nitrate, TKN, benthic chlorophyll a, sestonic chlorophyll a ³ Includes total chloride, and conductivity ⁴ Includes total suspended solids and volatile suspended solids		

Biological Assemblage Sampling

Biological assemblages in the 2020 study area included fish and macroinvertebrates at 20 instream locations for fish and 19 locations for macroinvertebrates. Biological and habitat sampling adhered to a summer-early fall index period of June 16-October 15 for fish and July 1-September 30 for macroinvertebrates. A habitat evaluation was performed at all fish sites using the QHEI (Ohio EPA 2006) and a site description accompanied the Illinois EPA multihabitat macroinvertebrate samples. All sampling occurred during periods of summer-fall base flows.

Fish Assemblage Methods

Fish were collected at 20 sites using both boatable and wading electrofishing units. Larger sites located on the mainstem Des Plaines River were sampled using an inflatable raft mounted electrofishing unit in a downstream direction, and sites located in Mill Creek and North Mill

Creek were sampled using a tote barge mounted or a bank set long-line electrofishing units. Wadeable sites were sampled at a distance of 0.20 km in a downstream to upstream direction, headwater sites were sampled at a distance of 0.15 km in a downstream to upstream direction, and boatable sites were sampled at a distance of 0.50 km in an upstream to downstream direction. Tote barge and bank set long-line units used pulsed D.C. current produced by a Smith-Root 2.5 GPP control box powered by a 2.5 kW alternator and a 5.5 HP gasoline mounted engine. The raft mounted unit used pulsed D.C. current produced by a Smith-Root 5.0 GPP control box powered by a 5.0 kW alternator and an 11.0 HP gasoline mounted engine. Deference was given to the most effective method given the prevailing site and water characteristics. A dip net was used to assist in the capture of stunned fish. A two or three-person crew consisting of a fish crew leader and one or two field technicians conducted the sampling under summer-fall base flow conditions.

Captured fish were placed in a live well or live net for processing at the end of each site. Water was regularly replaced and/or aerated to maintain adequate oxygen levels in the water to minimize mortality. Samples from each site were processed by enumerating and recording weights by species and by life stage (young-of-the-year, juvenile, and adult) on a standard water resistant field sheet. The incidence of external anomalies was recorded following procedures outlined by Ohio EPA (1996, 2015a) and refinements made by Sanders et al. (1999). Fish were released back into the water after they were identified to species, examined for external anomalies, and weighed either individually or in batches. Larval fish, if collected, were not included in a sample and fish measuring less than 25 mm in length were generally excluded as a matter of practice (excepting adults of small species). All sites were marked with GPS coordinates (beginning, middle, and end of a sampling reach) and site data was recorded on a standard field form.

While the majority of captured fish were identified to species in the field, any uncertainty about field identification required vouchering for laboratory identification. Voucher specimens were preserved in borax buffered 10% formalin solution and labeled by date, stream, and geographic identifier (e.g., river mile and site number). Regional ichthyology keys were used including the Fishes of Illinois (Smith 1979) and updates available through the Illinois Natural History Survey (INHS). Scientific nomenclature followed Page et al. (2012). Vouchers were deposited at The Ohio State University Museum of Biodiversity (OSUMB) in Columbus, OH. The data were used to calculate the Illinois Fish Index of Biotic Integrity (fIBI; Smogor 2000, 2005) as the primary assessment of fish assemblage quality and the Modified Index of Well-Being (MIwb; Ohio EPA 1987) in addition to expressions of species richness and relative abundance.

Macroinvertebrate Methods

Macroinvertebrate methods followed the Illinois EPA multi-habitat method (Illinois EPA 2011c,d) at all sites (Table 3). The Illinois EPA multi-habitat method involves the selection of a sampling reach that has instream and riparian habitat conditions typical of the assessment reach. Sampling reach requirements included flow conditions that approximate typical summer base flows, the absence of highly influential tributary streams, the presence of one riffle/pool sequence or analog (i.e., run/bend meander or alternate point-bar sequence) if present, and a

length of at least 300 feet and a maximum of up to 800 feet. The collection of macroinvertebrates was accomplished with a d-frame dip net in all bottom-zone and bank-zone habitat types that occurred within a sampling site. Water conditions must allow a sampler to apply the 11-transect habitat-sampling method or to estimate with reasonable accuracy via visual or tactile cues the amount of each of several bottom-zone and bank-zone habitat types. All sites were marked with GPS coordinates (beginning and end of a sampling reach) and site data was recorded on a standard field form.

Multi-habitat macroinvertebrate samples were field preserved in 10% formalin. Upon delivery to the MBI lab in Hilliard, OH the preserved samples were transferred to 70% ethyl alcohol. Laboratory procedures followed the Illinois EPA (2011e) methodology which requires the production of a 300-organism subsample from a gridded tray following a scan and pre-pick of large and/or rare taxa. Taxonomic resolution was at the lowest practicable resolution for the common macroinvertebrate assemblage groups such as mayflies, stoneflies, caddisflies, midges, and crustaceans, which goes beyond the genus level requirement of Illinois EPA (2011g). However, the calculation of the Macroinvertebrate IBI (mIBI) adhered to the Illinois EPA methods by using genera as the benchmark level of taxonomic resolution for mIBI scoring. Analyses using the lowest resolution data were accomplished.

Area of Degradation and Attainment Values

The Area of Degradation Value (ADV) and Area of Attainment Value (AAV) were used to demonstrate the trajectory of the biological assemblages and aquatic life use attainment through time and within pollution impact reaches of the Upper Des Plaines River northern tributaries, Year 4, study area. The ADV (Yoder and Rankin 1995; Yoder et al. 2005) was originally developed impact reach that is defined by the impact from one or more sources downstream through an initial zone of impact and through zones of partial to complete recovery. For results that surpass a biocriterion, this is expressed as an Area of Attainment Value (AAV) that quantifies the extent to which the minimum attainment criterion is surpassed. The ADV/AAV correspond to the area of the polygon formed by the longitudinal profile of fIBI and mIBI scores and the straight line boundary formed by their respective biocriterion, the ADV below and the AAV above. The computational formula (after Yoder et al. 2005) is:

$$ADV/AAV = \sum [(aIBI_a + aIBI_b) - (pIBI_a + pIBI_b)] * (RM_a - RM_b), \text{ for } a = 1 \text{ to } n, \text{ where;}$$

aIBI_a = actual IBI at river mile a,
 aIBI_b = actual IBI at river mile b,
 pIBI_a = IBI biocriterion at river mile a,
 pIBI_b = IBI biocriterion at river mile b,
 RM_a = upstream most river mile,
 RM_b = downstream most river mile, and
 n = number of samples

The average of two contiguous sampling sites is assumed to integrate biological assemblage status for the distance between the points. The intensive pollution survey design typically

positions sites in close enough proximity to sources of stress and along probable zones of impact and recovery so that meaningful changes are adequately captured. We have observed biological assemblages as portrayed by their respective indices to change predictably in proximity to major sources and types of pollution in numerous instances (Ohio EPA1987a; Yoder and Rankin 1995; Yoder and Smith 1999; Yoder et al. 2005). Thus, the longitudinal connection of contiguous sampling points produces a reasonably accurate portrayal of the extent and severity of impairment in a specified river reach as reflected by the indices (Yoder and Rankin 1995). The total ADV/AAV for a specified river segment is normalized to ADV/AAV units/mile for making comparisons between years and rivers. The ADV is calculated as a negative (below the biocriterion) expression; the AAV is calculated as a positive (above the biocriterion) expression. Each depicts the extent and degree of impairment (ADV) and attainment (AAV) of a biological criterion, which provides a more quantitative depiction of quality than do pass/fail descriptions. It also allows the visualization of incremental changes in conditions that may not alter the pass/fail status, but are nonetheless meaningful in terms of incremental change over space and time. In these analyses, the Warmwater Habitat (WWH) biocriterion for the fish and macroinvertebrate indices, which vary by use designation and ecoregion, were used as the threshold for calculating the ADV and AAV for the upper Des Plaines River mainstem. The General Use for aquatic life biocriteria for the fIBI and mIBI represent the minimum goal required by the Clean Water Act (CWA) for the protection and propagation of aquatic life, thus these were used as a standard benchmark for the ADV/AAV analyses herein.

Habitat Assessment

The QHEI (Rankin, 1989, 1995; Ohio EPA, 2006) was utilized as the primary habitat assessment methodology at each site. The assessment was conducted as a part of the fish assemblage method by the fish crew leader, who is trained and experienced in using the QHEI, during the initial sampling pass. The QHEI is comprised of six categories of habitat that influence the quality of the aquatic biota. The sum of the six categories ranges from 0-100, with scores of 60 or greater generally being regarded as sufficient to support the General Use for aquatic life while scores below 45 indicate substantial deficiencies in habitat for aquatic communities. These rules-of-thumb have been altered by the NE IL IPS analyses and the newer thresholds were used to assess habitat quality. A QHEI matrix (Rankin 1995) showing the occurrence of good and modified attributes was also developed to evaluate the overall capacity of the stream habitat to support the General Use at each site and to diagnose potential deficiencies that might be limiting to the aquatic assemblages.

Data Management

All data were managed by MBI in internal databases that permit ready access and analysis. Biological and habitat data is stored in a routine based on the Ohio ECOS format that MBI uses for all biological data management tasks. Biological data analysis included the calculation of the Illinois fish and macroinvertebrate IBIs for determining General Use aquatic life status and the

accompanying data attributes to enhance the diagnosis of impairments. Habitat data were analyzed using the QHEI and also via a QHEI attributes matrix to aid in assessing habitat related impairments. Summaries of fish species and macroinvertebrate taxa relative abundance, QHEI metrics, and QHEI field sheets by site and by sampling date are provided in Appendices A-C.

Determining Use Attainability

Illinois EPA offers a single aquatic life use designation that applies to all rivers and streams through the General Use provision of the Illinois WQS. This is the presumed use applicable to all rivers and streams in Illinois which includes the 2020 study area. An assessment of aquatic life use attainability is therefore not a routine outcome of a biological and water quality assessment and was not performed herein. However, the data collected is adequate to determine if the habitat is a limiting factor for any instances of non-support. Stressor thresholds, Restorability, and Susceptibility/Threat factors, and other analyses based on five narrative categories consisting of excellent, good (meets General Use), fair, poor, and very poor quality were completed. These boundaries simulate the application of a tiered aquatic life use (TALU) framework.

Causal Diagnosis

Describing the causes and sources associated with observed biological impairments relies on an interpretation of multiple lines of evidence including water chemistry data, sediment chemistry data, habitat data, effluent data, land use data, and biological response signatures (Yoder and Rankin 1995; Yoder and DeShon 2003). Thus the assignment of associated causes and sources of biological impairment in this report represents the association of impairments (based on response indicators) with stressor and exposure indicators using linkages to the bioassessment data based on previous experiences with analogous situations and impact types. This was done by relating exceedances of chemical thresholds such as chronic and acute water quality criteria and relevant biological effects thresholds for water and sediment chemistry from the NE IL IPS tool and dashboard to further refine the relative importance of categorical and/or parameter specific causes. The reliability of the identification of associated causes and sources is increased where other such prior associations have been observed. This process relies on multiple lines of evidence concerning the biological response which is the ultimate measure of success in water quality management. The NE IL IPS derived exceedance thresholds for chemical and habitat parameters used in the causal analyses were also used in the tabular and graphical presentation of the chemical water and sediment results. When combined with the Restorability and Susceptibility/Threat rankings this improved the certainty of the assignment of causes and sources to an observed biological impairment.

Hierarchy of Water Indicators

A carefully conceived ambient monitoring approach, using cost-effective indicators comprised of ecological, chemical, and toxicological measures, can ensure that all relevant pollution sources are judged objectively based on environmental results. A tiered approach that links the results of administrative actions with true environmental measures was employed in our

analyses. This integrated approach is outlined in Figure 3 and includes a hierarchical continuum from administrative to true environmental indicators. The six “levels” of indicators include:

- Level 1 - actions taken by regulatory agencies (permitting, enforcement, grants);
- Level 2 - responses by the regulated entity (treatment works, pollution prevention);
- Level 3 - changes in discharged quantities (pollutant loadings);
- Level 4 - changes in ambient conditions (chemical/physical water quality, habitat);
- Level 5 - changes in uptake and/or assimilation (tissue contamination, biomarkers, assimilative capacity); and,
- Level 6 - changes in health, ecology, or other effects (ecological condition, human and wildlife health).

In this process, the results of administrative activities (levels 1 and 2) are linked to water quality (levels 3, 4, and 5) which translates to a response (level 6). The administrative steps taken by Illinois EPA to issue NPDES permits (Level 1) and the steps taken by the permit holders (Level 2) are easily described and quantified. Quantifying changes in the loadings of pollutants (Level 3) can be affected by the quality and completeness of the effluent monitoring which includes the capture of stressors that affect the receiving streams. Likewise, documenting changes in ambient conditions (Level 4) can also be affected by the quality and completeness of the chemical/physical monitoring that not only includes the parameters but also the spatial design in relation to sources of pollution. This in turn informs about how pollution sources tax the

Completing the Cycle of WQ Management: Assessing and Guiding Management Actions with Integrated Environmental Assessment

Indicator Levels

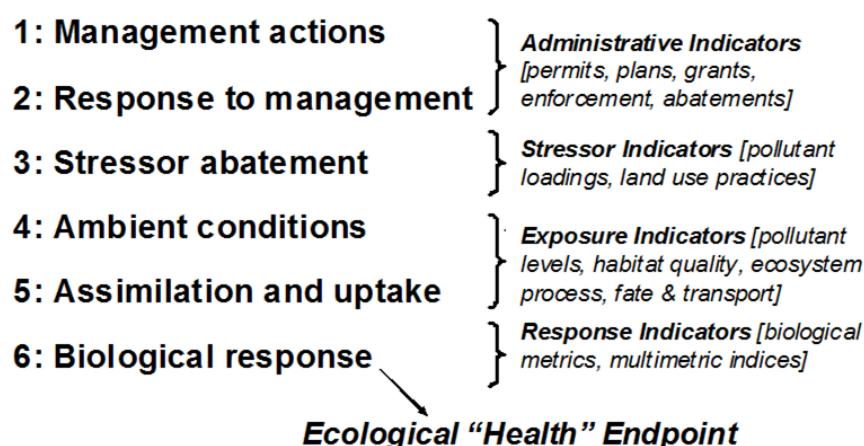

Figure 3. The hierarchy of administrative and environmental indicators which can be used to support monitoring and assessment, reporting, and an evaluation of the effectiveness of pollution controls on a receiving stream. This is attorned after a model developed by U.S. EPA (1995a,b) and enhanced by Karr and Yoder (2004).

assimilative capacity (Level 5) of a receiving stream. The end result of all the above is portrayed by the response in the biological indicators which is expressed as attainment or non-attainment of the Illinois General Use aquatic life thresholds for the fish and macroinvertebrate IBIs (Illinois EPA 2016). Symptoms expressed by the biota beyond the index scores can be useful in aiding the causal diagnosis as a feedback loop in the hierarchy of indicators process.

Superimposed on this hierarchy is the concept of stressor, exposure, and response indicators.

- *Stressor* indicators generally include activities that have the potential to degrade the aquatic environment such as pollutant discharges (permitted and unpermitted), land use effects, and habitat modifications.
- *Exposure* indicators are those which measure the effects of stressors and can include whole effluent toxicity tests, tissue residues, and biomarkers, each of which provides evidence of biological exposure to a stressor or bioaccumulative agent.
- *Response* indicators are generally composite measures of the cumulative effects of stress and exposure and include the more direct measures of community and population response that are represented here by the biological indices which comprise the Illinois EPA biological endpoints.

Causal Associations

Describing the causes and sources associated with biological impairments in the study area involved the interpretation of multiple lines of evidence that included water chemistry, sediment chemistry, habitat, and effluent data, a general knowledge about upstream land uses, and biological response signatures within the biological data itself. The assignment of causes and sources of biological impairment result from the association of the impairment with exceedances of water quality criteria or other response-based thresholds and the proximity to sources of pollution. This process was strengthened by the availability of regionally derived stressor effect thresholds from the NE IL IPS (MBI 2020a) that classified stressor levels into excellent, good, fair, poor, and very poor categories.

RESULTS - CHEMICAL/PHYSICAL WATER QUALITY

Chemical/physical water quality in the 2020 study area was characterized by grab sample data collection for the water column 4-6 times at each Tier 1-3 sites during summer-fall base flows and by hand held meter only at Tier 4 sites. Commonly detected chemical parameters were compared either to the criteria in the Illinois WQS, Illinois EPA non-standard benchmarks, reference benchmarks, and/or biologically derived thresholds from the NE Illinois IPS tool and IPS Dashboard (MBI 2020a). As such, the chemical/physical data herein serves as an indicator of the degree of exposure and stress in support of using the biological data to assess the attainment of designated aquatic life uses and to assist in assigning associated causes and sources. Parameter groupings included field, demand, ionic strength, nutrients, heavy metals, and organic compounds. Bacteria data were collected by grab samples and were used primarily

to determine the status of recreational uses in accordance with U.S. EPA National Water Quality Criteria (U.S. EPA 2012).

Flow Regime

The flow regime of the 2020 study area during the period of May 1 – October 31 for 2016, 2018, and 2020 monitoring years was based on the U.S. Geological Survey gauge on the Des Plaines River at Gurnee, IL (05528000; Figure 4). The flow regime was comparatively higher in 2020 than in 2016, but peak flows were lower in 2020 as opposed to 2018. Flows during the 2020 sampling period did not fall below the $Q_{7,10}$ and were consistently above the 50th percentile. Flows were at acceptable levels in August-September to conduct the biological survey.

Point Source Effluent Quality

Point source discharges of treated wastewater are a significant contribution of pollutant loadings to the upper Des Plaines River mainstem with design average flows of 78.7 MGD

Figure 4. Daily flow measured at the USGS gauge on the Des Plaines River (USGS 05528500) near Gurnee, IL during the calendar years 2016, 2018, and 2020. The horizontal lines are the flood stage, 75th percentile, 50th percentile, and the seven-day, ten year ($Q_{7,10}$) critical low flows. The span of biological collection in 2020 is indicated by shaded bars.

(MGD; or 146.2 cubic feet/second [cfs]) among seven (7) major wastewater treatment plants (WWTPs; Table 4). This total comprises 79.8% of the $Q_{7,10}$ flow of 37 cfs⁴ at the USGS Gurnee Gage and 57.1% of the median flow (110 cfs at the USGS Gurnee Gage). In 2020, the annual average discharge flow totaled 47.2 MGD (73.0 cfs) of treated wastewater (60% of the average design flows) which comprised 48% of the median flow (110 cfs at the USGS Gurnee Gage). As a result, the upper Des Plaines is considered to be “effluent dominated” which consists primarily of discharged treated wastewater and runoff from urban and agricultural areas (Onnis-Hayden et al. 2006). The NSWRD Waukegan, NSWRD Gurnee, and Lake Co. DPW Des Plaines facilities comprised 41-96% of the flow and loadings discharged to the Des Plaines River. A major exception was for $\text{NH}_3\text{-N}$ where Libertyville comprised 45% of the total loadings with the other three facilities contributing 41% of the total $\text{NH}_3\text{-N}$ load. Summaries of 2020 flow and loads from each facility follow in the order of occurrence along the Des Plaines River mainstem from upstream to downstream (Figure 5).

Lake Co. DPW Mill Creek WWTP

The Lake Co. Department of Public Works (DPW) Mill Creek WWTP discharged an annual average flow of 0.7 MGD (NPDES Permit No. IL0071366) which was 1.4% of the total among the seven (7) major treatment plants that directly impact the mainstem of the Des Plaines River (Table 4; Figure 5). The Mill Creek WWTP discharges to Mill Creek one mile upstream of the confluence with the Des Plaines River and it is the uppermost major facility on the mainstem. The design average flow (DAF) for the facility is 0.9 million gallons per day (MGD) and the design maximum flow (DMF) for the facility is 2.1 MGD. Treatment consists of screening, grit removal, activated sludge, sedimentation, filtration, ultraviolet disinfection, sludge handling facilities, and biological phosphorus removal with chemical addition as a backup system. In terms of 2020 effluent quality, the Mill Creek WWTP discharged the lowest proportion of loadings of CBOD_5 (1.8%), TSS (2.2%), $\text{NH}_3\text{-N}$ (1.4%), $\text{NO}_3\text{-N}$ (1.2%), and total P (0.4%; Figure 4).

NSWRD Waukegan WRF

The North Shore Water Reclamation District (NSWRD) Waukegan Water Reclamation Facility (WRF) discharged an annual average flow of 17.5 MGD (NPDES Permit No. IL0030244) which was 37.1% of the total among the seven (7) major treatment plants that directly impact the mainstem of the Des Plaines River (Table 4; Figure 5). The design average flow (DAF) for the facility is 22.0 million gallons per day (MGD) and the design maximum flow (DMF) is 44.0 MGD. Treatment consists of screening, grit removal, excess flow treatment, Imhoff tanks, primary settling, two-stage activated sludge, phosphorus removal, rapid sand filters, and ultraviolet (UV) disinfection. Sludge treatment includes gravity belt thickening, belt press dewatering, drying, and landfill disposal/land application. The NSWRD is a member of the Des Plaines Watershed Workgroup (DRWW). In 2020 the Waukegan WRF discharged the highest proportion of loadings of CBOD_5 (24.8%) TSS (32.5%), and $\text{NO}_3\text{-N}$ (38.6%), and the second highest loadings of $\text{NH}_3\text{-N}$ (17.5%). Total P (11.4%) was the third highest among the seven treatment plants (Figure 5).

Figure 5. Proportions of effluent flow (MGD) and pollutant loadings (lbs./day) discharged by seven (7) major WWTPs to the mainstem Des Plaines River in 2020. Proportions and loadings are based on the annual averages of each parameter. Discharges are listed in order from upstream to downstream in the inset table (bottom).

NSWRD Gurnee WRF

The NSWRD Gurnee Water Reclamation Facility (WRF) discharged an annual average flow of 12.0 MGD (NPDES Permit No. IL0035092) which was 25.4% of the total among the seven (7) major treatment plants that directly impact the mainstem of the Des Plaines River (Table 4; Figure 5). The design average flow (DAF) for the facility is 23.6 million gallons per day (MGD) and the design maximum flow (DMF) for the facility is 47.2 MGD. Treatment consists of screening, grit removal, excess flow treatment, two-stage activated sludge, primary and secondary clarifiers, biological phosphorus removal, tertiary filtration, UV disinfection, sludge processing and drying. In terms of 2020 effluent quality the Gurnee WRF discharged the third highest proportion of loadings of CBOD₅ (15.1%), TSS (22.0%), and NH₃-N loading (11.2%), and the highest proportion of NO₃-N (38.6%) and total P (49.4%; Figure 5).

Libertyville WWTP

The Libertyville WWTP discharged an annual average flow of 2.8 MGD (NPDES Permit No. IL0029530) which was 5.9% of the total among the seven (7) major treatment plants that directly impact the mainstem of the Des Plaines River (Table 4; Figure 5). The design average flow (DAF) for the facility is 4.0 million gallons per day (MGD) which is also the design maximum flow (DMF). Treatment consists of screening, grit removal, primary sedimentation, activated sludge, final clarifiers, filtration, disinfection (chlorination and dechlorination), sludge handling facilities, and excess flow treatment and disinfection. Libertyville is a member of the Des Plaines Watershed Workgroup (DRWW). In terms of 2020 effluent quality the Libertyville WWTP discharged the highest proportion of loadings of NH₃-N (44.8%), the third lowest proportion of loadings of TSS (7.5%), fourth lowest total P (1.4%), and second lowest loadings of CBOD₅ (10.2%) and third highest NO₃-N (8.3%; Figure).

Mundelein WWTP

The Mundelein WWTP discharged an annual average flow of 2.4 MGD (NPDES Permit No. IL0029530) which was 5.1% of the total among the seven (7) major treatment plants that directly impact the mainstem of the Des Plaines River (Table 4; Figure 5). The design average flow (DAF) for the facility is 4.0 million gallons per day (MGD) and the design maximum flow (DMF) for the facility is 5.0 MGD. Treatment consists of screening, grit removal, primary sedimentation, activated sludge, final clarifiers, filtration, disinfection (chlorination and dechlorination), sludge handling facilities, and excess flow treatment and disinfection. Mundelein *is not* a member of the Des Plaines Watershed Workgroup (DRWW). In terms of 2020 effluent quality the Mundelein WWTP discharged the third lowest proportion of loadings of NH₃-N (7.9%) and total P (1.2%), the fourth lowest loadings of NO₃-N (6.3%) and CBOD₅ (13.1%), and second lowest TSS (3.5%; Figure).

Lake Co. DPW New Century Town WWTP

The Lake Co. Department of Public Works (DPW) New Century Town WWTP discharged an annual average flow of 3.1 MGD (NPDES Permit No. IL0022071) which was 6.6% of the total among the seven (7) major treatment plants that directly impact the mainstem of the Des

Plaines River (Table 4; Figure 5). The design average flow (DAF) for the facility is 2.9 million gallons per day (MGD) and the designed maximum flow (DMF) for the facility is 6.0 MGD. Treatment consists of screening, grit removal, activated sludge, settling, filtration, disinfection, and sludge handling facilities. Lake Co. is a member of the Des Plaines Watershed Workgroup (DRWW). In terms of 2020 effluent quality the Lake Co. Des Plaines WWTP discharged the third lowest proportion of loadings of CBOD₅ (10.4 %), fourth lowest proportion of TSS (9.0%), and second lowest NO₃-N (2.4%), NH₃-N (5.2%), and total P (1.0%; Figure 5).

Lake Co. DPW Des Plaines WWTP

The Lake Co. Department of Public Works (DPW) Des Plaines WWTP discharged an annual average flow of 8.6 MGD (NPDES Permit No. IL0022055) which was 18.2% of the total among the seven (7) major treatment plants that directly impact the mainstem of the Des Plaines River (Table 4; Figure 5). The Des Plaines WWTP discharges to Aptakisic Creek 0.8 miles upstream of the confluence with the Des Plaines River and it is the lowermost major facility on the mainstem. The design average flow (DAF) for the facility is 16.0 million gallons per day (MGD) and the design maximum flow (DMF) for the facility is 51.8 MGD. Treatment consists of screening, grit removal, activated sludge, settling, filtration, disinfection, and sludge handling facilities. Lake Co. is a member of the Des Plaines Watershed Workgroup (DRWW). In terms of 2020 effluent quality the Lake Co. Des Plaines WWTP discharged the second highest proportion of loadings of CBOD₅ (24.6%) and TSS (23.3%), third highest NH₃-N (11.9%), fourth highest NO₃-N (8.0%), and the second highest of total P (35.7%; Figure 5).

Water Column Chemistry

The water column chemistry results were analyzed for spatial (longitudinal) patterns made possible by the pollution survey design in the Des Plaines River mainstem and at a single site in Mill Creek and two sites in North Mill Creek. The results were screened for exceedances of Illinois WQS, Illinois non-standard benchmarks, regional reference benchmarks, and biological effect thresholds derived from the NE Illinois IPS were assessed in the Year 4 study area.

Exceedances of Biological Effect and Reference Thresholds

The principal purpose of chemical sampling in a bioassessment is to provide data that supports the interpretation and the assignment of associated causes of biological impairments. Chemical exceedances of biological effect thresholds are essential to that process and have previously included the Illinois WQS, regional reference benchmarks, and other national and regional biological effects compendia. Some of these consist of correlations between concentrations of substances that correspond to biological quality gradients across significant geographical areas while others are toxicological endpoints derived from laboratory studies.

Two regional studies that have been used previously included correlative effects levels of different chemicals by the DuPage River Salt Creek Working Group (DRSCWG; Miltner et al. 2010) in northeastern Illinois and the Metropolitan Sewer District of Greater Cincinnati (MSDGC; MBI2015) in southwest Ohio. NOAA Screening Quick Reference Tables (SQRT; Buchman 2008) were also used especially for chemicals that are not covered in the Illinois WQS.

The more recently available NE Illinois IPS (MBI 2020) thresholds for water column chemical, sediment, and habitat and land use parameters appear in Tables 7-9 have replaced the use of the previous thresholds. They are now the first choice for assessing these variables in the tables and figures of the results as each is applicable in the Des Plaines Year 4 study area. NE Illinois derived sediment chemical thresholds are provided in Table 8 and were supplemented with the threshold and probable effect levels (TEL and PEL) established by MacDonald et al. (2000) and IEPA (Short 1998). Habitat and land use related variables appear in Table 9. The severity of exceedances of these values offered by the multiple narrative classes (i.e., excellent, good, fair, poor, and very poor) were used to support the assignment of causes of biological impairment provided that there was a logical linkage of the chemical exceedance with the biological impairment. The chemical water column grab sample results are displayed graphically and in tabular format (Table 10) for selected parameters and with exceedances of IPS derived effect thresholds. With the exception of D.O., there were no exceedances of parameters that have IEPA water quality criteria.

Demand and Nutrient Related Parameters

Demand and nutrient related parameters consist of those related to the discharges of treated and untreated sewage, organic enrichment from point and nonpoint sources, nutrient parameters and their effects, and physical parameters such as total suspended solids, turbidity, pH, and temperature.

Dissolved Oxygen (D.O.)

Exceedances of dissolved oxygen (D.O.) were assessed primarily with continuous data obtained from three (3) DRWW permanent Datasonde locations and additional short-term deployments at 12 locations during August. The data from the continuously deployed locations were used to evaluate the weekly and rolling average aspects of the IEPA D.O. criteria in addition to the seasonally varied minimums. Exceedances of the minimum D.O. (5.0 mg/L) occurred at site 13-6 (RM 109.3) in June for four (4) days, the 7-day minimum (4.0 mg/l) from August 14-21, and the 7-day average (<6.0 mg/l) on two separate occasions (June 29-July 6 and July 12 (Table 11). Exceedances of the minimum D.O. criteria was observed at site 13-1 (RM 94.2) for six (6) days in July and the 7-day average on two separate occasions in July (July 2-8 and July 12-24). The third Datasonde located at 16-4 (RM 80.0) had an exceedance of the 7-day average D.O. criterion during July 4-28. All of the significant exceedances occurred well upstream of the discharges of the largest loadings of oxygen demanding substances from municipal wastewater treatment facilities to the Des Plaines River mainstem. This data was further evaluated as symptom of excessive nutrient enrichment in the modified SNAP assessment at 13 sites which includes the short-term data obtained at 10 sites.

The short-term deployments of more numerous Datasonde continuous recorders in late August 2020 recorded exceedances of portions of the IEPA D.O. criteria (Figure 6). All of these deployments were made after August 1 hence the minimum was evaluated against the 3.5 mg/L criterion and the 6 mg/L 7-day average criterion. There was insufficient data to evaluate

Table 7. Biological effect thresholds derived from Northeast Illinois streams and rivers for selected water column parameters as part of the NE Illinois IPS development and used to assess results from the Year 4 Des Plaines River study area. The most limiting of the fish or macroinvertebrate assemblages for each parameter are indicated along with thresholds for excellent, good, fair, poor, and very poor biological condition along with FIT score (see Appendix D), sample N, and regional reference values for NE Illinois rivers and streams <350 mi.².

Parameter Code	Variable Name	Units	Parameter Group	Limiting Assemblage	FIT Score	Sample N	Thresholds by Narrative Condition Category					Reference Site Values (Median-2X IQR)	Reference Site N

Table 11. Exceedances of the different parts of the Illinois dissolved oxygen (D.O.) water quality standard among the three continuously operated Datasondes in the upper Des Plaines River during the summer-early fall period of 2020.

Site ID	River	Year	River Mile	Month/Date/Duration	Criterion	Narrative Standard
13-6	Des Plaines River	2020	109.3	June - #Days: 4	<5.0 mg/l	Not to exceed
13-6	Des Plaines River	2020	109.3	6/29 - 7/6	<6.0	7-day Average
13-6	Des Plaines River	2020	109.3	July - #Days: 11	<5.0 mg/l	Not to exceed
13-6	Des Plaines River	2020	109.3	7/12 - 7/24	<6.0	7-day Average
13-6	Des Plaines River	2020	109.3	8/14 - 8/21	<4.0 mg/l	7-day Minimum
13-1	Des Plaines River	2020	94.2	July - #Days: 6	<5.0 mg/l	Not to exceed
13-1	Des Plaines River	2020	94.2	7/2 - 7/8	<6.0	7-day Average
13-1	Des Plaines River	2020	94.2	7/12 - 7/24	<6.0	7-day Average
16-4	Des Plaines River	2020	80.0	7/4 - 7/28	<6.0	7-day Average

the weekly and rolling average aspects of the IEPA D.O. criteria, so the median was compared to the weekly average of 6.0 mg/L for screening purposes.

Exceedances of the 3.5 mg/L minimum criterion occurred only at 13-18 (RM 99.72), immediately upstream of the Wetland Research riffle. Wide D.O. swings were observed at 13-5 (RM 106.6), 13-18 (RM 99.72), and 13-19 (99.3) in which the median values ranged by more than 6.0 mg/L. Sites 13-5 is downstream of Rosecrans Rd, 13-18 is immediately upstream of the Wetland Research Riffle, and site 13-19 is immediately downstream of the Wetland Research Riffle. Exceedances of the 6.0 mg/L average occurred at three (3) sites 13-4 (RM 102.9), 13-3 (RM 98.7), and 16-6 (RM 87.1) with most values at 16-6 below the 6.0 mg/L 7-day average.

pH

pH reflects the degree to which a fluid is acidic or basic with 7.0 S.U. being neutral. Excessive nutrient enrichment can indirectly affect pH levels via increased algal activity and the associated photosynthesis and respiration. The natural cycle of photosynthesis during daytime and respiration during nighttime can be exaggerated leading to an increase in the diel flux of pH levels similar to how it affects D.O. (Zheng and Paul 2009). The pH values in the upper Des Plaines River survey area were recorded via grab samples at 20 locations during the summer-fall period and continuously using Datasonde units that were deployed for 4-5 days between August 21 and September 1, 2020. The latter was done at 12 sites in addition to the three (3) units that were continuously operated by DRWW beginning in June 2020. The permanently deployed Datasondes were deployed at sites 13-6 (RM 109.30), 16-7 (RM 84.60), and 16-4 (RM 80.00) for the first time in 2020. Sites 16-4 and 16-7 did not have pH data from the MBI Datasondes due to a failure of the pH probe during deployment resulting in pH data being available for 12 sites total. The upper Des Plaines Datasonde recorded median pH levels generally declined from >8.0 S.U. upstream to 7.5-8.0 S.U. downstream with the highest median and widest diel swing values being observed at site 13-6 in the highly modified upstream reach in the upper mainstem (Figure 7). Site 13-18 (RM 99.30) had the same median as at site 13-16, but with a lesser diel swing. The highest recorded maximum value was also observed at site 13-6 with the next highest value being observed downstream from the New

Figure 6. Dissolved oxygen (D.O.) concentrations (mg/L) measured continuously by Datasondes deployed for 3-4 day periods during August 21-24 and 24-27, 2020 at 13 locations in the 2020 and at 3 long term locations operated by DRWW. Box-and-whisker plots show the minimum, maximum, 25th and 75th percentiles, median, and outliers (>2 interquartile ranges from the median) values. The IEPA August-February minimum (3.5 mg/L) and the 7-day average D.O. criteria are shown by solid and dashed lines. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each.

Century Town WWTP (16-4). Slight increases in median pH values were observed downstream from the Mill Creek WWTP (13-18), and downstream from the Libertyville and Mundelein WRFs (16-7). A decline in the median pH was observed downstream from the Waukegan WRF (13-3) and a further decline downstream from the Gurnee WRF (13-2). The median pH values from the grab sample results ranged from 7.8-8.2 in the mainstem with the highest value occurring in the North Fork of Mill Creek at site 10-1 (RM 1.1) near the mouth (Table 10). Taken together, the continuous data results at all except site 13-6 reflected only slight to moderate effects from nutrient enrichment on pH.

Temperature

Temperature is a controlling factor for aquatic life, hence it is important to document the thermal regime and note any apparent alterations. Water temperature was likewise measured via grab samples at 20 sites and Datasondes at 15 locations, 12 of which were short-term deployments and three (3) that were continuously operated by DRWW. The continuous results are displayed a box-and-whisker plots that include a median, upper and lower quartile, maximum, minimum, and outlier values. Typically the potential for adverse thermal effects are evaluated based on the warmest period of the year and against temperature criteria that are intended to protect aquatic life. The highest summer temperatures were observed in the upper mainstem with the highest maximum at the upstream most site 13-6 (RM 109.30) and highest median at site 13-5 (RM 106.60) both of which are in the channel modified reach in the upper mainstem (Figure 8). Temperatures declined by 4.0-4.5°C at site 13-2 (RM 96.82) downstream from the NSWRD Gurnee WRF outfall. Temperatures increased from the low values at site 13-2 by 2.0-2.5°C at site 13-1 (RM 94.20) and remaining at that level through the remainder of the mainstem. The median values from the grab sample data ranged from a low of 20.9°C at site 13-1 (RM 94.2) to high value of 26.9°C at site 16-1 (RM 71.70; Table 10). Temperatures in Mill and North Mill Creeks ranged from a low of 22.2°C at site 10-1 (RM 1.10) in North Mill Creek to 26.1 at site 10-7 (RM 11.3) located 10.2 miles upstream. The results were evaluated against the Ohio EPA temperature criteria for similarly sized streams in the Ohio River drainage basin that include a summer period average and maximum criterion. The maximum criterion of 31.7°C is slightly more stringent than the Illinois General Use temperature standard of 32.2°C that applies between April-November. The two maximum values from the Datasonde results at sites 13-6 and 13-5 exceeded the summer average criterion of 29.4°C, but none of the remaining maximum values nor any of the median values approached that level.

Ammonia-Nitrogen (N)

Levels of ammonia-N were either below or just above or at the mean detection level (MDL) in 2016, 2017, and 2018 with no values that would suggest significant chronic or acutely toxic effects to aquatic life during those surveys. Mean values in 2020 were less frequently detected than in 2018, but at substantially higher concentrations at four (4) sites in 2020 (Figure 9; Table 10). Concentrations of ammonia-N in 2020 were below detection levels from the upstream most site (13-16) downstream to site 16-6 just upstream from the Libertyville WWTP. Downstream from this point mean values ranged from poor and very poor at sites 16-7 (RM 84.6), 16-8 (RM 82.9), and 16-3 (RM 76.7) and fair at site 16-4 (RM 80.0). The Mundelein and

Figure 7. pH values measured continuously by Datasondes deployed for 3-4 day periods during August 21-24 and 24-27, 2020 at 12 locations and continuous data at three locations in the 2020. Box-and-whisker plots show the minimum, maximum, 25th and 75th percentiles, median, and outlier (>2 interquartile ranges from the median) values. The shaded area is the range of the Illinois pH standard of 6.5-9.0 S.U. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each.

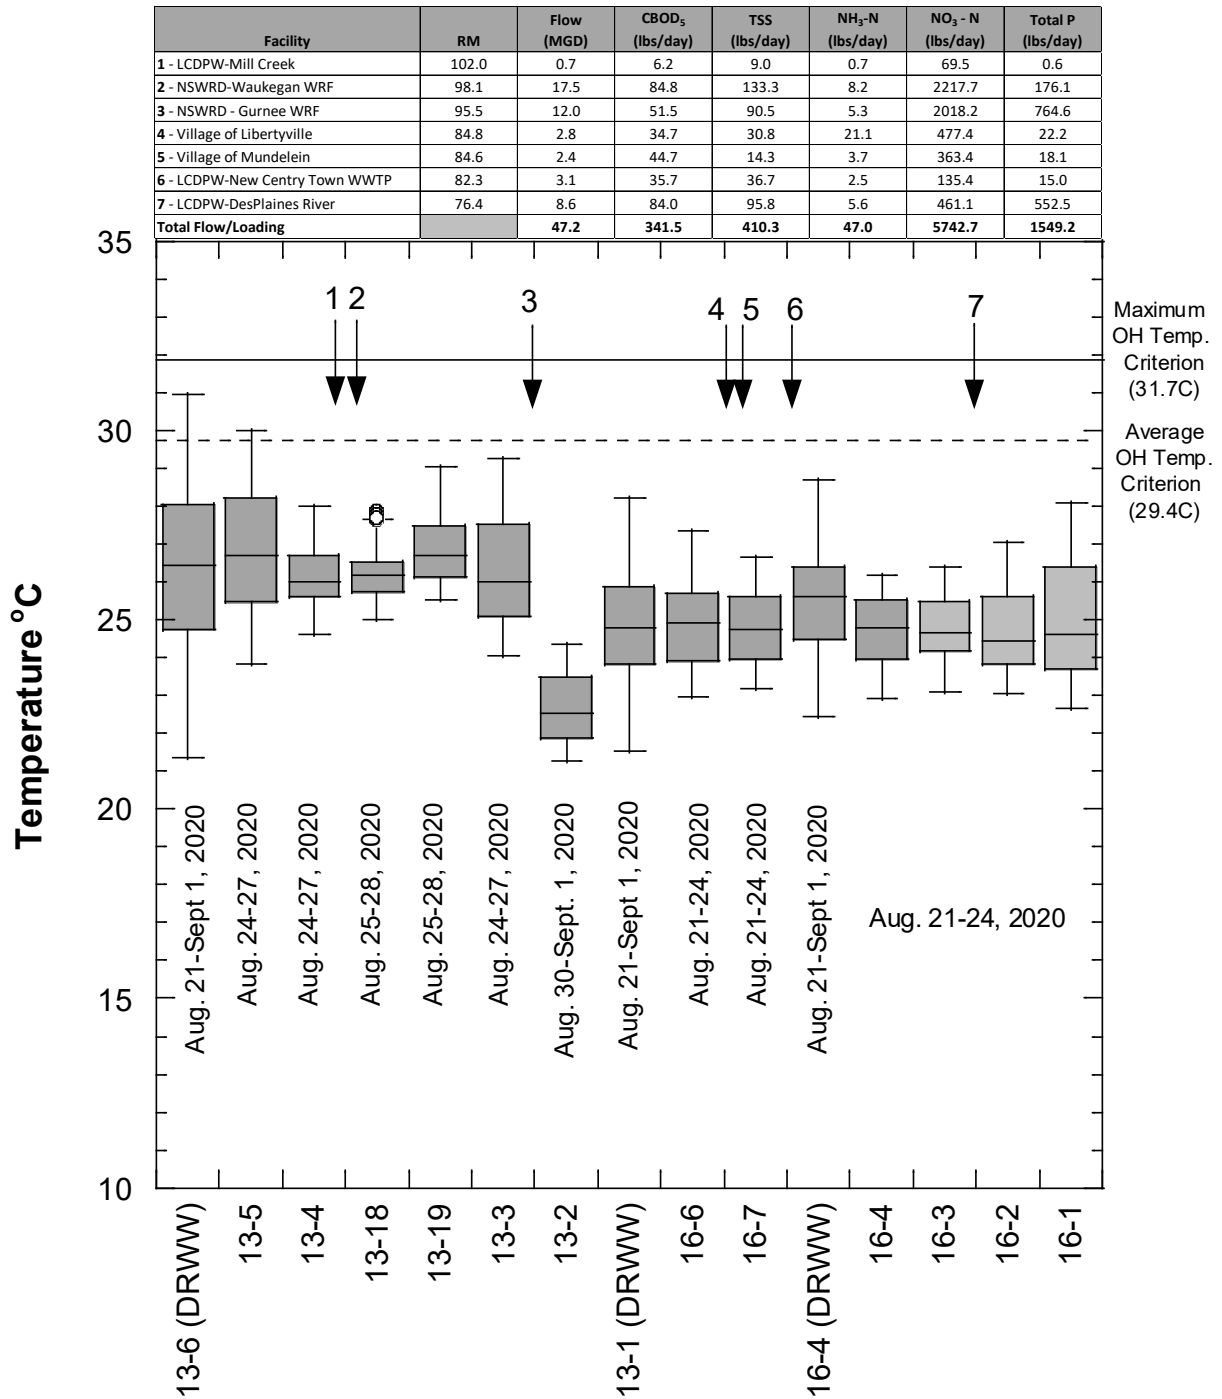

Figure 8. Temperatures measured continuously by Datasondes deployed for 3-4 day periods during August 21-24 and 24-27, 2020 at 12 locations and continuous data at three locations in the 2020. Box-and-whisker plots show the minimum, maximum, 25th and 75th percentiles, median, and outlier (>2 interquartile ranges from the median) values. The solid and dashed lines are the Ohio EPA maximum and average summer period criteria for similarly sized rivers and streams in the Ohio River basin. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each.

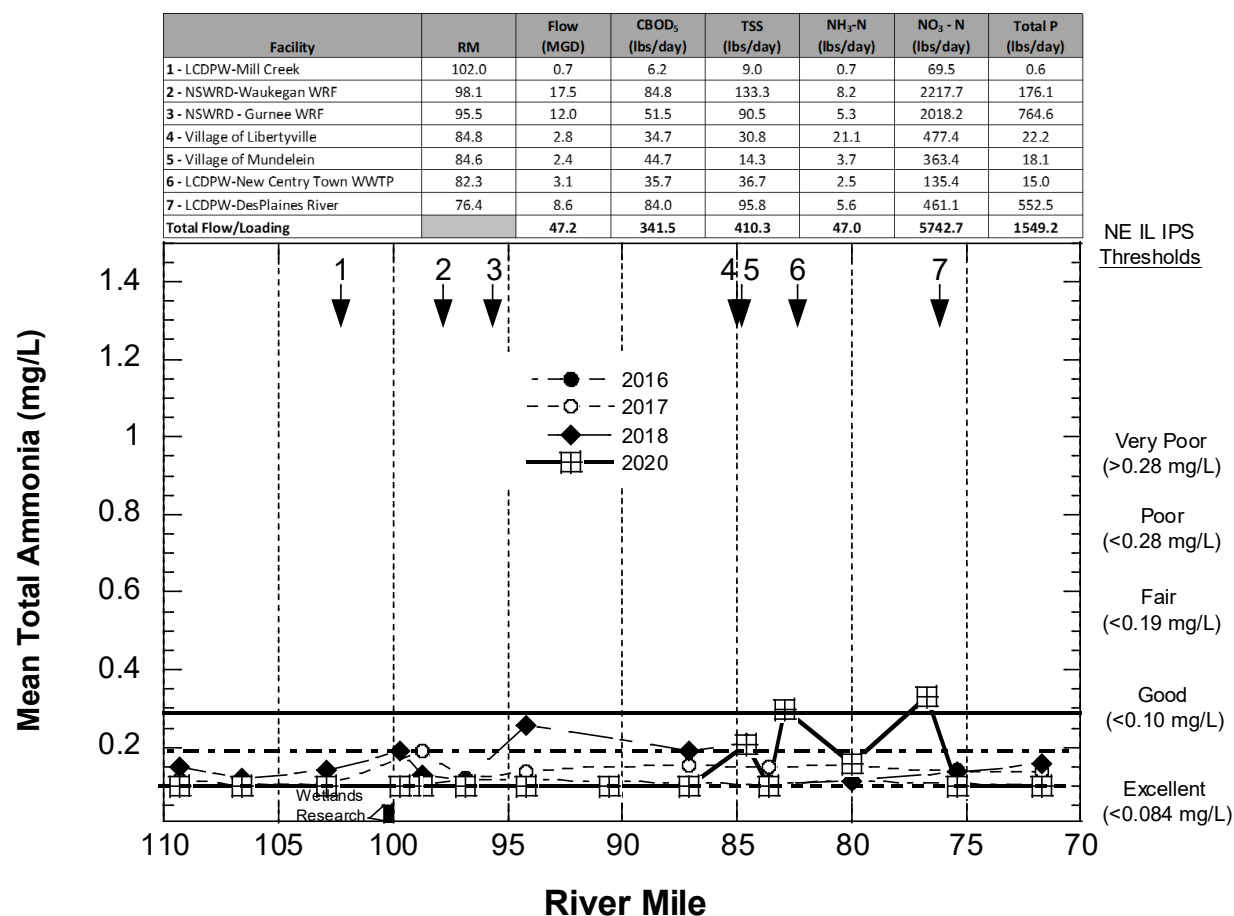

Figure 9. Concentrations of mean ammonia-N in the upper Des Plaines River mainstem during June-October 2016-2020. Dashed and solid lines represent IPS derived effect thresholds correlated with ranges of biological quality and as listed in Table 7. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each.

Libertyville WWTP outfalls are upstream from site 16-7, potentially indicating wastewater as the source of the elevated ammonia-N concentrations at sites 16-7 and 16-8. Indian Creek enters the Des Plaines River upstream from site 16-3 which had the highest mean of 0.33 mg/L and maximum value of 1.25 mg/L. DRWW recorded a total ammonia-N value of 3.34 mg/L in Indian Creek at site 15-9 on August 27, 2020 with higher values being recorded in prior years. However, this site is more than 10 miles upstream from the confluence with the mainstem so it is doubtful that these values are related to the elevated mean and maximum values observed at site 16-3 in 2020. Ammonia-N levels were low in Mill Creek with a mean of 0.10 mg/L and below the MDL at both sites in North Mill Creek (Table 10).

Total and Dissolved Phosphorus

Median total phosphorus levels based on grab samples in the mainstem ranged from good to fair in the IPS derived thresholds in all years 2016-2020. Median total P values in 2020 reflected a similar pattern to the values observed in 2017 and were about twice the 2018 median values downstream from the Wetland Research riffle (Figure 10). Median total P values in the highly modified section of the upper Des Plaines mainstem were just above the good range

downstream to site 16-7. The median declined into the good range downstream from Libertyville where it remained downstream to site 16-1. The longitudinal pattern that was indicative of wastewater treatment plant inputs in 2016 has not been observed since. Median total phosphorus levels ranged from good to excellent in Mill Creek and North Mill Creek (Table 10). Total phosphorus concentrations were below the excellent threshold at the upstream most site in North Mill Creek (10-7) with both sites in the lower section of North Mill (10-1) Creek and Mill Creek (11-2) below the good threshold. The dissolved form of inorganic phosphorus was also measured as orthophosphate in 2020 which was compared to the total P results (Figure 11). The results are reported as median values in Table 10 along with the difference between median total P and orthophosphate values at each site. Using a difference of 0.10 mg/L as a benchmark the differences were greatest in the upper mainstem between sites 13-6 (RM 109.3) and 13-19 (RM 99.72) which includes the channel and flow modified reach of the mainstem. The difference suggests that the fraction of total P that is readily available is lower than in the downstream effluent dominated reach of the mainstem. A large difference was also observed

Figure 10. Concentrations of median total phosphorus in the upper Des Plaines River mainstem during June-October 2016-2020. Dashed and solid lines represent IPS derived effect thresholds correlated with ranges of biological quality and as listed in Table 7. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each.

in the North Fork Mill Creek at site 10-1 (RM 1.10). The role of total P (and other indicators) as a contributor to overall nutrient enrichment effects was evaluated as part of the modified SNAP procedure (Ohio EPA 2015b) discussed later.

Dissolved phosphorus was analyzed for the first time in 2020 in support of NARP development for the upper Des Plaines mainstem POTWs. Median dissolved P generally tracked total P along the longitudinal continuum, but the difference between total and dissolved was greater upstream from the effluent dominated portion of the mainstem at most sites downstream from the NSWRD Waukegan WRF. This is an indication of the fraction of total P as dissolved P between nonpoint and point sources, the fraction as dissolved being higher with the latter in the mainstem. The Mill Creek and North Mill Creek dissolved P levels reflected nonpoint source inputs (Table 10).

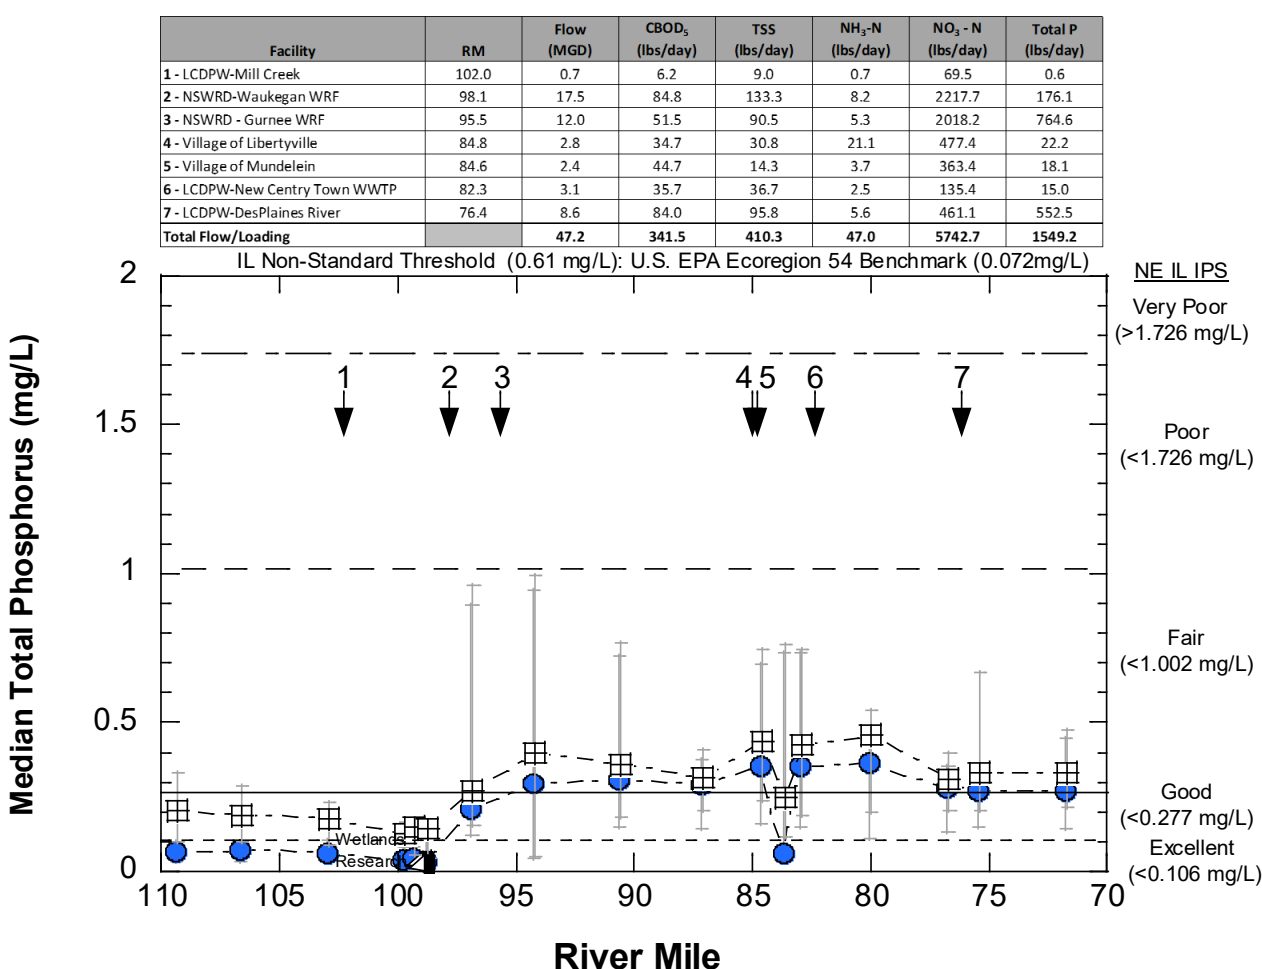

Figure 11. Concentrations of median total (square symbols) and dissolved phosphorus (blue symbols) in the upper Des Plaines River mainstem during June-October 2016-2020. Dashed and solid lines represent IPS derived effect thresholds for total P correlated with ranges of biological quality and as listed in Table 7. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each.

Total Nitrate-N ($\text{NO}_3\text{-N}$)

Median total nitrate-N concentrations were very low being mostly <1.00 mg/L in the upper mainstem downstream to site 13-2 (RM 96.82) located just downstream from the NSWRD Waukegan WRF where concentrations steadily increased downstream (Figure 12). Values were in the excellent range of the IPS thresholds at and upstream from site 13-2. The median value at site 13-1 (RM 94.2) downstream from the NSWRD Gurnee WRF increased into the fair range. The highest median values in the poor range were observed immediately upstream and downstream from the Libertyville and Mundelein WWTPs at sites 16-6 (RM 87.1) and 16-7 (RM 84.6) and downstream from the New Century Town WRF at site 16-4 (RM 80.00). The longitudinal pattern was similar to the 2016 and 2018 results except with consistently higher nitrate-N concentrations in the lower mainstem in 2020. Median total nitrate-N concentrations in the tributary sites were in the excellent range at each location (Table 10). The role of nitrate-N (and other indicators) as a contributor to overall nutrient enrichment effects was evaluated as part of the modified SNAP procedure (Ohio EPA 2015b) discussed later.

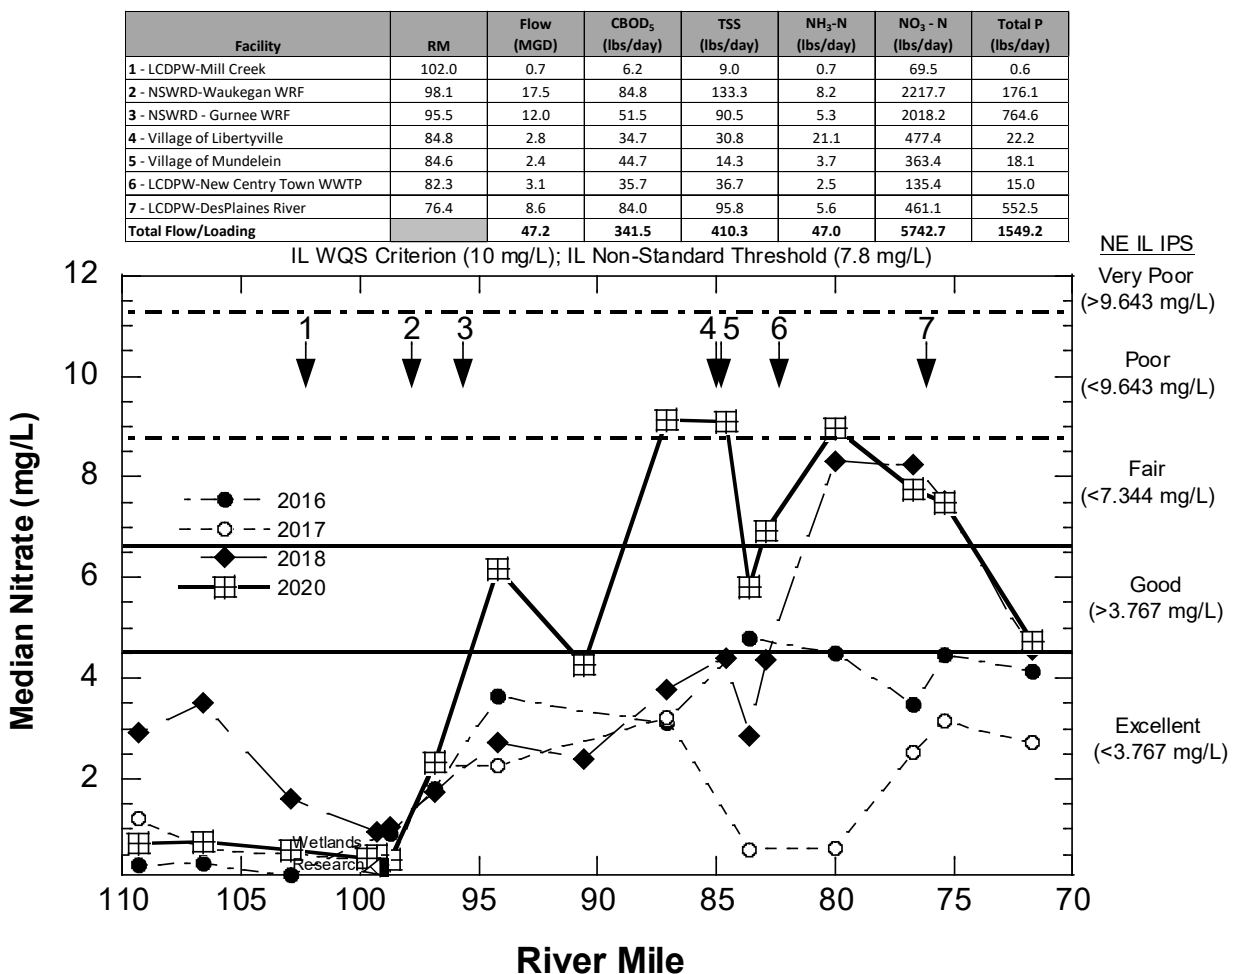

Figure 12. Concentrations (mg/L) of median nitrate-N in the upper Des Plaines River mainstem during June-October 2016-2020. Dashed and solid lines represent IPS derived effect thresholds correlated with ranges of biological quality and as listed in Table 10. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each.

Total Kjeldahl Nitrogen (TKN)

Organic nitrogen as measured by Total Kjeldahl Nitrogen (TKN), an indicator of the living or recently dead fraction of sestonic algae, is an informative indicator of nutrient enrichment. While TKN is not a direct effect parameter, it is indicative of the effects of organic enrichment by nitrogenous biomass. Median TKN values ranged from mostly fair to poor at three mainstem sites (Figure 13). The poor median TKN value of 1.68, 1.64, and 1.63 mg/L were observed at sites 13-5, 13-4, and 13-3 (Table 10). Overall, median concentrations of TKN were generally lower than in 2018, particularly in the wastewater effluent dominated reach of the mainstem. The longitudinal pattern in the 2020 resembled 2016 and 2017 in that all three years were lower than 2018. With the exception of borderline poor values in the upper modified reach, there was little variation in TKN concentrations. TKN values at the Mill and North Mill Creek sites were elevated in the fair range (Table 10). The role of TKN (and other indicators) as a contributor to overall nutrient enrichment effects was evaluated as part of the modified SNAP procedure (Ohio EPA 2015b).

Figure 13. Concentrations (mg/L) of median total Kjeldahl nitrogen (TKN) in the upper Des Plaines River mainstem during June-October 2016-20. Dashed and solid lines represent IPS derived effect thresholds correlated with ranges of biological quality and as listed in Table 6. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each.

Total Suspended Solids (TSS)

Total suspended solids (TSS) can reflect either inorganic suspended sediment and/or organic matter in the form of sestonic algae. Median concentrations of TSS ranged from poor in the highly modified section of the survey area to excellent downstream of the Wetland Research riffle with a steep decline in values between those two sites (Figure 14). The longitudinal pattern suggests that the input of treated wastewater generally coincided with decreased concentrations of TSS in the effluent dominated reach of the Des Plaines River. Very small spikes in TSS occurred in this latter reach, but were negligible compared to the comparatively elevated values in the upstream modified reach. Two exceedances of the poor threshold occurred at site 11-2 (RM 1.71) in Mill Creek and site 10-1 (RM 1.10) in North Mill Creek (Table 10). The role of TSS (and other indicators) as a contributor to overall nutrient enrichment effects was evaluated as part of the modified SNAP procedure (Ohio EPA 2015b).

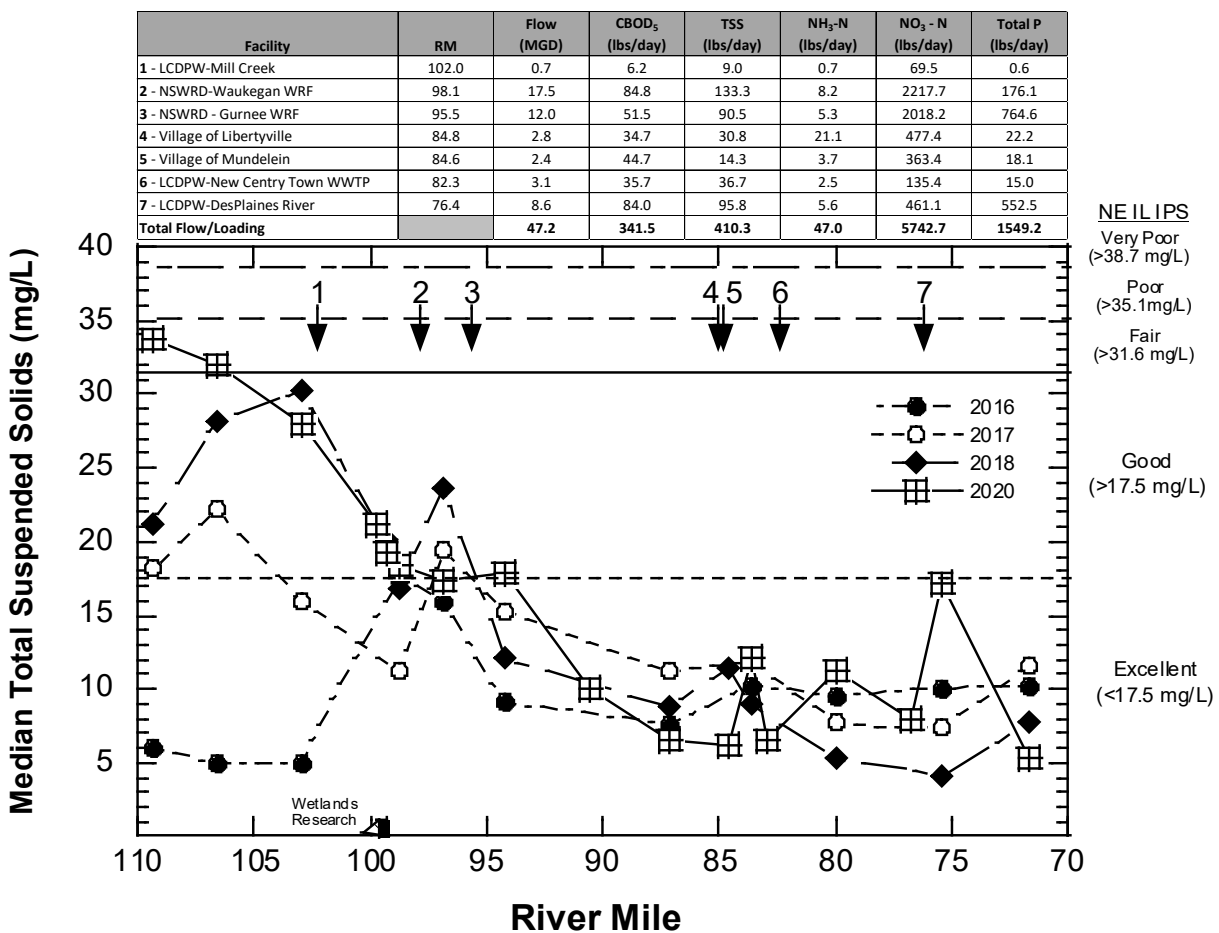

Figure 14. Concentrations (mg/L) of median total suspended solids (TSS, upper) in the upper Des Plaines River mainstem during June-October 2016-2020. Dashed and solid lines represent IPS derived effect thresholds correlated with ranges of biological quality and as listed in Table 10. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each.

Nutrient Effects Assessment

The impact of nutrients on aquatic life has been well documented (e.g., Allan 2004), but the derivation of criteria and their form and application are only just now emerging. Because of the widely varying efforts to develop nutrient criteria by the States, conflicting U.S. EPA oversight, and the potential cost of additional nutrient controls it has been a controversial issue (Evans-White et al. 2014). Unlike toxicants, the influence of nutrients on aquatic life is indirect and primarily via their influence on algal photosynthesis and respiration and the resulting increased magnitude of diel D.O. swings and by the oxygen demand exerted by algal decomposition. Nutrients can also affect food sources for macroinvertebrates and fish and the response of aquatic life to elevated nutrients is co-influenced by habitat (e.g., substrate composition), stream flow (e.g., scouring and dilution), temperature, and exposure of the water column to sunlight. Illinois is the leading state in terms of nitrogen (16.8%) and phosphorus (12.9%) loadings exported via the Illinois and Upper Mississippi Rivers to the Gulf of Mexico where an anoxic zone has developed (U.S. EPA 2008). In Illinois, as in neighboring Midwestern states that drain to the Mississippi River, efforts are underway to modernize nutrient water quality criteria. However, nutrient export is not the only concern – local impacts are also important and the focus of this evaluation is on reach scale effects in the upper Des Plaines River mainstem.

The combined effects of nutrient enrichment were assessed to better integrate the preceding descriptions of concentrations of each of the key nutrient related parameters and the other non-chemical factors described previously. A multiparameter approach modified from the Ohio SNAP methodology (Ohio EPA 2015a) and the newer large rivers methodology (Miltner 2018), and as described in the Methods section, was employed in a progressive manner as has been done previously in other DRWW assessments since 2017. The results are detailed in a matrix that shows the fish and macroinvertebrate IBIs, the QHEI score, total P, nitrate-N, TKN, the maximum and minimum D.O. (based on Datasondes), the width of the diel D.O. swing, benthic chlorophyll a (as biomass), sestonic chlorophyll a and an overall rating of the degree of nutrient enrichment based on the frequency and magnitude of exceedances of thresholds for the aforementioned indicators and parameters expressed as the total SNAP score for 13 sites in the 2020 study area (Table 12). The SNAP score results from summing parameters specific SNAP scores that are weighted higher for five primary indicators – the fIBI, mIBI, diel D.O. swing, benthic chlorophyll a, and sestonic chlorophyll a, less for three secondary parameters – QHEI, total phosphorus, and the maximum D.O., and the least for four tertiary parameters – total nitrate-N, minimum D.O., TSS, and TKN and normalizing the values to a 0-100 scale with nutrient enrichment increasing inversely to the total SNAP score (see bottom of Table 12). The overall degree of nutrient enrichment effects are represented by five narrative ratings of Enrichment Status that results from the degree to which each of the nutrient related parameters and SNAP indicators exceeded their respective primary, secondary, and tertiary thresholds. The Highly Enriched and Enriched narratives are assigned where the indicators are exceeded in terms of the number and magnitude of poor and very poor exceedances that are associated with a biological impairment. The Possible Nutrients narrative is assigned where there a predominance of fair exceedances, but an insufficient number and/or magnitude of poor or very poor exceedances to warrant an Enriched status. Hence it serves as an indication

Table 12. Results of applying a modified Stream Nutrient Assessment Procedure to the 2020 Year 4 study area. Descriptions of how each result reflects the degree of nutrient enrichment effects and which results in an assignment of overall enrichment status are shown at the bottom of the matrix along with the source of the thresholds for each primary (blue shaded), secondary (green shaded), and tertiary (tan shaded) parameter. The weighted SNAP score for each parameter and the total SNAP score for deriving the overall enrichment status are shown adjacent to each site parameter value. Biological sampling sites that lacked continuous D.O. data were not assigned an overall enrichment status, but were included for comparison of the biological attainment status, habitat quality, and nutrient parameters that were available. Sestonic chlorophyll a scores for sites with no sestonic chlorophyll a values were based on adjacent sites.

where a threat for adverse effects from nutrient enrichment exists. The Not Nutrients narratives rule out nutrient effects as a cause of impairment and it is always assigned to sites that exhibit full attainment of the General use biocriteria. Sites that do not attain the General Use biocriteria are their narratives based on the total SNAP score (Table 12).

The updated SNAP results for 2020 showed that overall nutrient enrichment status was the most serious in the upper mainstem particularly in the flow and habitat modified reach where the Highly Enriched status was assigned to site 13-6 (RM 109.30) and Enriched to site 13-5 (RM 106.60). The only other Enriched status in the 2020 study area was at site 13-19 just downstream from the Wetland Research riffle and impoundment. Possible Nutrients status assignments bracketed the Wetlands Research riffle and included sites 13-4 (RM 102.90) upstream from Mill Creek and site 13-18 I the Wetlands Research impoundment. The only other Possible Nutrient sites occurred immediately downstream at sites 13-3 (RM 98.60) and 13-2 (RM 96.82) which bracket the NSWRD Waukegan WRF effluent. The remaining sites were all rated as Not Nutrients Good due primarily to a lack of fair, poor, or very poor exceedances of the primary SNAP indicators even though total P concentrations increased into the fair range beginning at site 13-2 and extending downstream through the remainder of the study area.

The frequency of exceedances of the primary SNAP and most of the secondary and tertiary indicators declined in a downstream direction which shows a diminishing effect of nutrients away from the modified reach of upper mainstem being exacerbated locally by the Wetland Research impoundment. The 2020 results in the mainstem were similar to the 2018 results which was the first application of the SNAP method to the upper Des Plaines River mainstem albeit using a more qualitative approach to determining the enrichment status. The 2020 results confirmed the conclusion of the 2018 assessment that the predominant source of nutrient enrichment is presumably from nonpoint sources in the upper watershed and the effects of which are exacerbated by the combination of hydrological and physical modifications that are prevalent in the upper mainstem and tributaries. The entry of large volumes of permanent flow via the major wastewater treatment facilities seems to mitigate most of the negative effects that emanate from the upper watershed.

Ionic Strength Parameters

Ionic strength parameters are generally in the form of dissolved solutes that can be delivered to rivers and streams in runoff events and point source effluents and some are associated with urban runoff specifically. These include parameters measured in the water column and commonly include conductivity, total dissolved solids, and ions such as chlorides and sulfate. Typically our analyses have been geared to urban parameters which includes common heavy metals, but these were not analyzed in the water nor sediment samples in 2020.

Chlorides

In temperate climates such as exist in northern Illinois, dissolved materials in the form of chlorides are an emerging problem because they accumulate in soils and shallow groundwater

and have been documented to reach concentrations that can threaten and impair aquatic life. Of particular concern in urban areas with high road density is the concentration of chlorides from winter road salt applications and point source loadings from water treatment blowdown. Kelly et al. (2012) identified a steadily increasing trend in chloride levels in the Illinois River at Peoria where the median increased from 20 mg/L in 1947 to nearly 100 mg/L in 2004 with high values in the 1940s of <40 mg/L rising to >300 mg/L by 2003. Chlorides do not exhibit a simple runoff and export mode of effect, but rather accumulate in near surface groundwater (Kelly 2008), soils, and land surfaces adjacent to streams. Seasonal studies have shown that elevated summer concentrations are correlated with higher and acute concentrations during late winter and spring periods (Kaushal et al. 2005). Research in New England (Kaushal et al. 2005) and Minnesota (Novotny et al. 2008) show that chlorides can accumulate in watersheds and that there is a strong association between high winter and elevated summer concentrations. Novotny et al. (2008) identified that 78% of the road salt applied in a Minnesota watershed accumulated in a given year and contributed to an increase in summer chloride concentrations.

Median total chloride concentrations (mg/L) in the upper Des Plaines mainstem ranged from good to just exceeding fair values in 2020 (Figure 15). The 2020 median values were the lowest of the four years of data 2016-18 and 2020. Chloride levels were in the good range downstream to site 16-6 (RM 87.1) downstream from which all except one site exceeded the lower fair range. The general pattern was a moderate increase in a downstream direction as the mainstem emerged from agricultural and suburban land uses in the upper watershed to increasingly urbanized land uses in downstream watersheds (especially the tributaries) and effluent dominance. Median chloride values were the highest during the low flow year of 2016 while the 2020 values were lower than in 2017-2018, which had somewhat higher flows. Median chloride values were in the good range at sites 11-2 (RM 1.71) in Mill Creek and 10-1 in North Mill Creek (RM 1.10). The median in North Mill Creek at site 10-7 (RM 11.3) was in the fair range (Table 10).

Conductivity

Dissolved materials are also measured by specific conductance or conductivity which is depicted in Figure 16 for continuous data and Figure 17 and Table 10 for grab sample data. The continuous conductivity data showed that most sites with values exceeding the good IPS threshold and some sites with comparatively higher values in the fair, poor, and very poor ranges. Sites 13-18 (RM 99.72), 16-7 (RM 84.6), and 16-1 (RM 71.7) had poor and very poor values which all occurred downstream from wastewater discharges. The downstream most site (16-1) is located adjacent to the Chicago Executive Airport and downstream from Buffalo Creek. The site downstream from the Libertyville and Mundelein WWTPs (16-7) had conductivity values primarily in the very poor range which potentially reflect those wastewater discharges to the mainstem. The site in the Wetland Research impoundment had consistently poor values with very poor maximum and outlier values. This site is located downstream of the confluence of Mill Creek which receives effluent from the Lake Co. DPW Mill Creek WRF. The three upper sites (13-6, 13-5, and 13-4) in the habitat and flow modified reach had the lowest values in the study area and were the only sites to not be influenced by a major wastewater discharge.

Figure 15. Concentrations (mg/L) of median total chloride in the upper Des Plaines River mainstem during June-October 2016-2020. Dashed and solid lines represent IPS derived effect thresholds correlated with ranges of biological quality and as listed in Table 7. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each.

Median conductance values ($\mu\text{S}/\text{cm}$) based on grab samples from the mainstem showed a similar response to that exhibited by chloride (Figure 17), but none of the poor and very poor exceedances revealed by the continuous results (Figure 16). Median conductance values in 2020 ranged from fair to good and followed a pattern of increase from upstream to downstream as the watershed changed from agricultural and suburban land uses to a prevalence of urban land uses, which alone does not suggest inputs by point sources. The longitudinal plot shows the 2020 median conductance values being the lowest compared to the previous years despite flows being lower than in 2017-2018. The highest median values in 2016 occurred under substantially lower flows. An examination of the maximum conductivity grab sample values shows a different result with all maximums exceeding the fair threshold in the upper mainstem and increasing markedly to the poor range beginning at site 13-1 (RM 94.20) and peaking into the very poor range beginning at site 16-7 (RM 84.60) and extending to site

Figure 16. Specific conductance ($\mu\text{S}/\text{cm}$) measured continuously by Datasondes deployed for multiday periods during mid-August at 15 locations in the 2020 study area. Box-and-whisker plots show the minimum, maximum, 25th and 75th percentiles, median, and outlier (>2 interquartile ranges from the median) values. The IPS thresholds for five narrative ratings are shown by solid and dashed lines. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each.

Figure 17. Median specific conductance in the upper Des Plaines River mainstem during June-October 2016-20. Dashed and solid lines represent IPS derived effect thresholds correlated with ranges of biological quality and as listed in Table 6. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each.

16-2 where the maximum remained in the very poor range. This reach of river is dominated by wastewater effluent where the maximums better reflect the continuous results. The difference between the median and maximum values suggests that the poor and very poor values are intermittently present and most likely due to point source inputs.

Median conductivity values in Mill Creek and North Mill Creek were in the excellent and good ranges reflecting background conditions (Table 10). Maximum values were in the fair and a single site (11-3) located well upstream in in North Mill Creek with a poor value. Still, these maximum values were well below those observed in the effluent dominated reach of the mainstem.

Physical Habitat Quality for Aquatic Life – QHEI

The physical habitat of a stream or river is a primary determinant of biological quality and potential. Streams in the glaciated Midwest, left in their natural state, typically offer pool-run-riffle sequences, moderate to high sinuosity, and well-developed channels with deep pools, heterogeneous substrates, and cover in the form of woody debris, hard substrates, and aquatic macrophytes. Lower gradient streams may not offer as distinct riffle habitats and are oftentimes run and glide dominated, but can still offer a diversity of substrates, well developed pool habitats, and well developed instream cover features associated with woody debris and aquatic macrophytes. The Qualitative Habitat Evaluation Index (QHEI) categorically scores basic components of stream and riverine habitat into ranks according to the degree to which those components are found compared to a natural state, or conversely, in an altered or modified state. In the Upper Des Plaines River study area, QHEI scores and physical habitat attributes were recorded in conjunction with the fish sampling conducted at each site.

Des Plaines River 2020 Mainstem Habitat Assessment Results

Habitat quality in the upper Des Plaines River ranged from poor (3 sites) to good (2 sites) in 2020 with the majority of the mainstem sites in the upper fair range (Figure 18). The upstream most sites scored in the low fair and poor range (42.0-53.0). This was the result of the extensive hydrological and physical modifications in the upper mainstem and watershed. The poor QHWEI score at site 13-18 (RM 99.72) was due to the impounded habitat formed by the Wetland Research artificial riffle. The incremental decline in QHEI scores in the upper modified reach between 2018 and 2020 was due to an increased predominance by muck and silt substrates and the reduction in instream cover at site 13-6 (RM 109.3). Sites downstream from the Wetland Research riffle and through the remainder of the mainstem scored considerably higher and followed a similar trend to previous years, ranging from the mid-fair to upper-good range (Figure 18). There has been an incremental decline in QHEI scores between 2016 and 2020 in the lower mainstem beginning at site 16-5 (RM 83.60) from good and marginally good QHEI scores to consistently fair scores.

QHEI Attributes Matrix 2020

High influence modified attributes were present only at the four sites in the upper modified reach which resulted in the poor and low-fair QHEI scores (Table 13). High influence attributes included silt/muck substrates (sites 13-6, 13-5, 13-4, 13-18), sparse or no instream cover (sites 13-6 and 13-5), and no recovery from channelization (sites 13-5 and 13-4). These high influence attributes have increased since 2016 and 2018 (MBI 2017, 2020). Moderate influence modified attributes were numerous with the highest number (8) occurring at sites 16-2 (RM 75.4) and 16-3 (RM 76.7). The highest ratios of modified to good attributes continues to occur at the sites upstream of the Wetland Research riffle (4.50) at 13-6 and 13-5. The ratio of modified:good attributes was fair (>2.00) at two of the upper modified reach sites and poor (>4.00) at the two upstream most sites. These sites also had a high number of moderate influence modified attributes ranging from 5-7 the latter a poor result. Modified: good ratios >2.00 generally indicate an extent of habitat modification and predominance of modified attributes that would

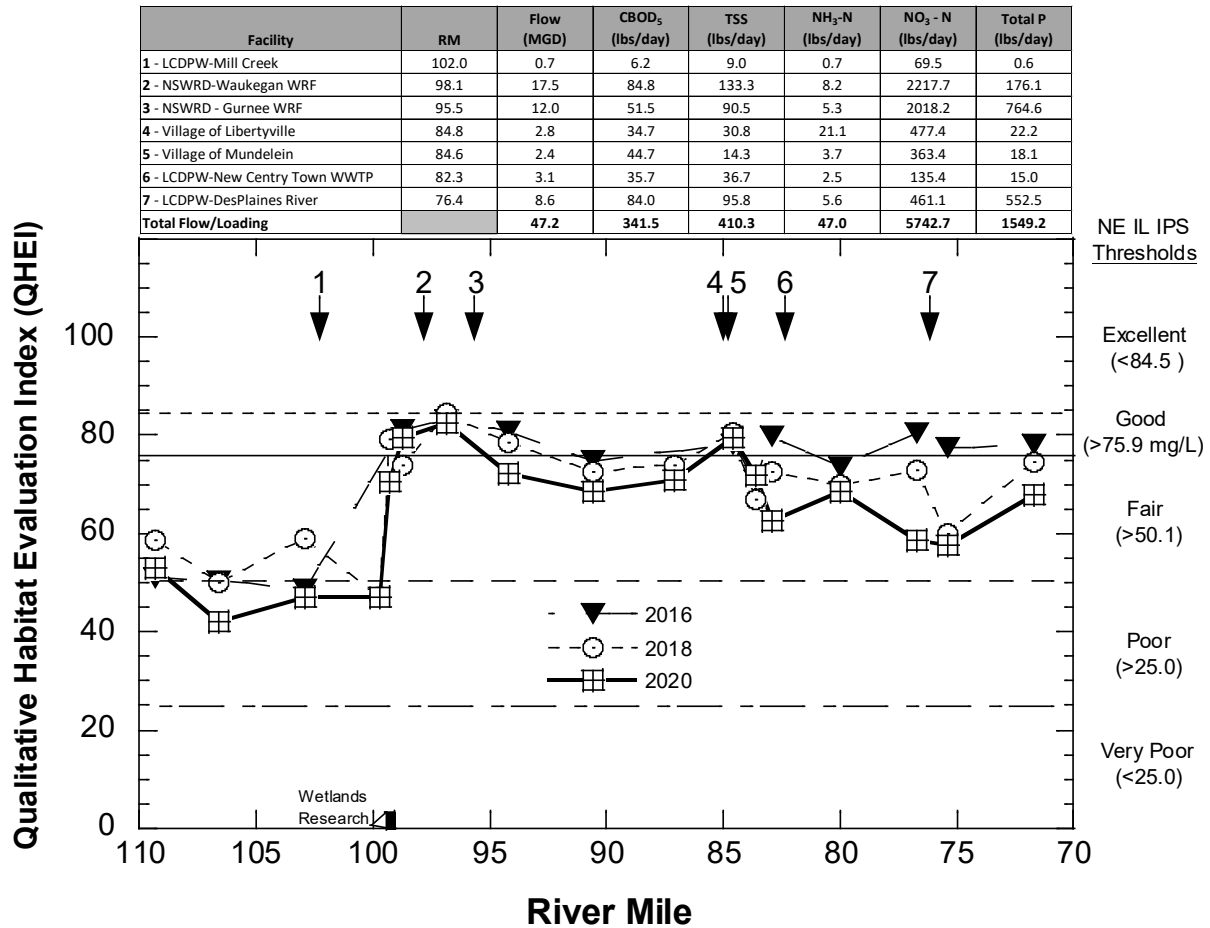

Figure 18. Qualitative Habitat Evaluation Index (QHEI) scores in the upper Des Plaines River mainstem in 2016, 2018, and 2020. The IPS narrative ranges of QHEI scores from excellent to very poor are indicated by solid and dashed lines. A key to sources (arrows and numbers) is in the table above the figure along with flows and loads from each.

require direct mitigation to reverse. It also means that meeting the General Use biocriteria would likely be precluded by habitat regardless of water quality conditions raising concerns about use attainability (Rankin 1995). The sites with modified:good ratios <2.00 is the result of having fewer modified attributes coupled with enough good attributes to offset the negative influence of the modified attributes. Fast current types were absent except at 13-2 (RM 96.82) and 16-7 (RM 84.6), reflecting the low gradient of the upper Des Plaines River mainstem. Sand substrates were observed at all sites excluding the three (3) most upstream sites that had muck/silt substrates. Moderate to high silt cover, moderate-extensive embeddedness, moderate-extensive riffle embeddedness, and fair-poor development were also the most commonly moderate influence modified attributes observed during the 2020 survey. An increase in the number of good habitat attributes offset the number of modified attributes downstream from the Wetland Research riffle with modified:good ratios <2.00 at all sites except sites 16-2 (RM 76.70) and 16-3 (RM 75.40).

Table 13. QHEI matrix of good and modified habitat attributes for sites in the upper Des Plaines River Year 4 study area during 2020. QHEI scores are shaded in accordance with IPS derived ranges; blue – excellent; green – good; yellow – fair; orange – poor; red – very poor. Ratios of poor and good attributes and modified:good ratios are shaded in accordance with the narrative categories at the bottom of the table.

Mill Creek and North Mill Creek 2020 Habitat Assessment Results

The three tributary sites that were a part of the 2020 study area were likewise assessed for habitat quality with the QHEI. The single site in Mill Creek (11-2) and downstream site in North Mill Creek (10-1) had fair habitat scores of 75.5 and 63.0, respectively (Table 11). The upstream site in North Mill Creek (10-3) had poor habitat quality with a QHEI score of 42.5. High influence modified attributes were observed only at site 10-3 consisting of no recovery from channelization, silt-muck substrates, and no sinuosity. Moderate influence modified attributes included moderate-high silt cover and moderate-extensive embeddedness at all three tributary sites. Modified:good attribute ratios were 0.38 (good) and 1.50 (good) in Mill Creek (site 11-2) and the downstream North Mill Creek (site 10-1), respectively. The modified:good ratio was 4.00 at the upstream North Mill Creek site (10-3). Habitat in Mill Creek at site 11-2 has remained fairly stable with QHEI scores of 79.0 in 2016 (MBI 2017) and 80.0 in 2017 (MBI 2018). In North Mill Creek QHEI scores at the downstream site (10-1) varied from 70.0 in 2016, 59.0 in 2017, and 63.0 in 2020 with somewhat elevated modified:good ratios in 2017 (2.00) and 2020 (1.50). The upstream site in North Mill Creek declined markedly in 2020 from QHEI scores of 52.0 in 2016 and 59.0 in 2017. The modified:good ratios were 1.20 in 2016, 1.67 in 2017, and elevated to 4.00 in 2020 and indication of declining habitat quality over time.

Biological Assemblages – Macroinvertebrates

There were 130 unique macroinvertebrate taxa collected in the upper Des Plaines River mainstem in 2020 (Appendix B). This is an increase from 103 (2016) and 104 (2018) taxa collected in previous surveys. The predominant taxa were more facultative than indicative of poor or good water quality. The most numerous was the genus *Oligochaeta* (segmented worms), followed by *Tricorythodes* sp. (a Mayfly taxon), *Corbicula fluminea* (Asiatic clams), *Gammarus* sp. (a Crustacean), and *Baetis intercalaris* (a Mayfly taxon; Table 14).

Des Plaines River 2020 Macroinvertebrate Assemblage Results

Macroinvertebrate assemblage quality in the upper Des Plaines River mainstem ranged from fair to good with fair results primarily being observed in the upper section of the survey area (Figure 17). Seven (7) of the 16 mainstem sites met the mIBI General Use biocriterion of 41.8, four (4) fewer than in 2018. The six (6) upstream most sites were all impaired - three (3) sites upstream from the Wetland Research riffle and the three (3) sites downstream. The site located in the Wetland Research pool was not sampled by the macroinvertebrate crew due to the inability to collect a multihabitat sample due to non-wadeable depths in the impoundment. The mIBI increased steadily downstream from the Wetlands Research riffle to site 13-2 (RM 96.82) where the mIBI of 41.2 just missed General Use and site 13-1 (RM 94.60) downstream from the NSWRD Waukegan WRF where the General Use mIBI was attained. Only two mIBI values fell below the General Use at site 16-8 (RM 82.9) downstream from the Libertyville and Mundelein WWTPs and site 16-1 (RM 71.70) downstream from Buffalo Creek. An increase in the total number of taxa, Mayfly taxa, intolerant taxa, and percent EPT taxa. No macroinvertebrate samples were collected at 10-7 (RM 11.3), the most upstream site in North Mill Creek.

Table 14. The fifteen (15) most abundant macroinvertebrate taxa collected in the upper Des Plaines River mainstem including sites collected, numbers collected, taxa group, functional group, and taxa tolerance assignments.

Taxa Code	Taxa Name	Sites Collected	Number Collected	Taxa Group	IL Functional Group	IL Tolerance Score

Taxa Group: N - Non-Insect; MA - Mayfly; O - Odonata; CA - Caddisfly; D - Dipteran; T - Tribe Tanytarsini; CO - Coleoptera
 IL Functional Group: CG - Collector/Gatherer; PR - Predator; CF - Collectors/Filterers; SH - Shredder; SC - Scraper
 IL Tolerance Score Ranges from 0 (Least Tolerant) to 10 (Most Tolerant); CG* the genus *Gammarus* does not have a group listed, but the common *Gammarus* species found are listed as CG

Table 15 lists the mIBI, selected mIBI metrics, and other macroinvertebrate assemblage attributes two of which are key biological response signatures associated with toxic impacts (%toxic tolerant taxa) and organic enrichment (%organic enrichment tolerant taxa; Yoder and DeShon 2003). Poor and very poor responses for all except two results occurred upstream from site 13-2 (RM 96.82) which is just upstream from the NSWRD Waukegan WRF discharge. None of the aforementioned sites met the General Use mIBI biocriterion. Only a single very poor result occurred, this for %organic enrichment taxa at site 13-19 (RM 99.3) downstream from the Wetland Research riffle. Poor results for the same response indicator occurred in the upper mainstem at sites 13-6, 13-5, and 13-3. Other poor results at site 13-2 and upstream included %EPT at five of six sites, %tolerant taxa at three of six sites, and a low number of intolerant taxa at a single site. The good numbers of taxa and the absence of any toxic responses suggest an impairment due to organic enrichment that is exacerbated by the modified habitat and hydrologic regime in the upper mainstem. Only one (1) site exceeded the fair threshold (13-1) for %toxic tolerant taxa, while all other sites ranged from good to excellent. The total number of taxa collected at each site ranged from 22-32 taxa. The number of EPT taxa ranged 2-10 with all except 13-6 and 13-5 reflecting good conditions. The % EPT taxa ranged from 2.8-67.3% with six (6) sites of good quality, four (4) sites of fair quality, and five (5) sites of poor quality. The number of intolerant taxa ranged from 1-6, with half the sites not exceeding the good threshold, three (3) sites in the poor range, and the remainder (5) reflecting fair conditions. Of

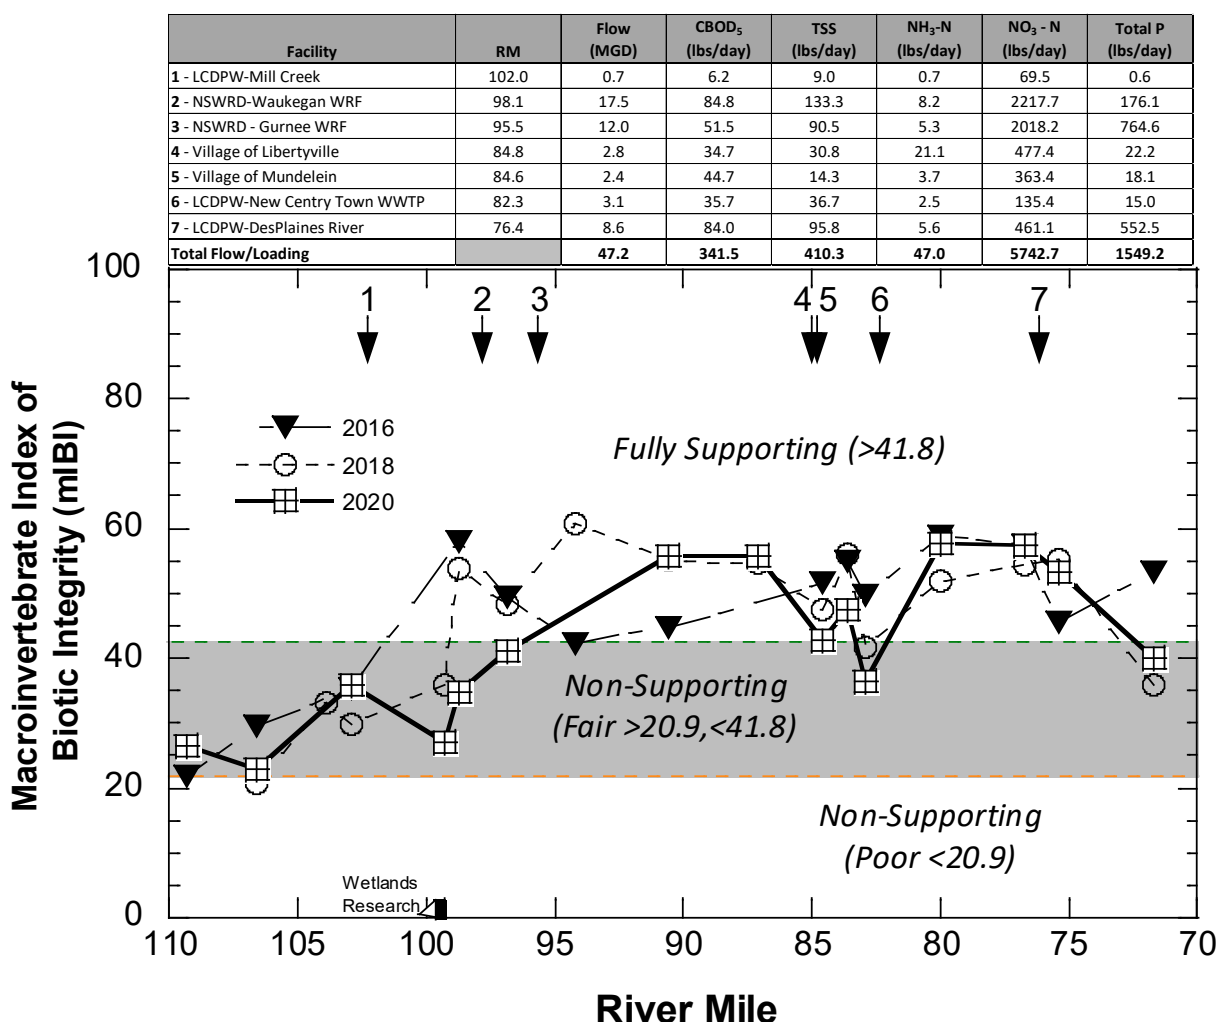

Figure 19. Illinois macroinvertebrate IBI scores in the upper Des Plaines River mainstem in 2016, 2018, and 2020. IEPA thresholds for determining full support, non-support-fair, and non-support-poor of the General Use for aquatic life are indicated by dashed lines and grey shading. A key to sources (arrows and numbers) is in the table above the figure along with flows and loads from each.

the eight (8) sites that did not meet the General Use biocriterion, five (5) possessed poor values of %EPT, and three (3) possessed poor values of %EPT and %tolerant taxa.

Mill Creek and North Mill Creek 2020 Macroinvertebrate Assemblage Results

Macroinvertebrates were sampled at a single site each in Mill Creek (11-2) and North Mill Creek (10-1) in 2020. Both had mIBI scores that met the General Use biocriterion (Table 15). The 2020 mIBI of 53.3 in Mill Creek at site 11-2 was a significant improvement from the 2016 results that had a fair mIBI of 25.3 (no sample was collected at 11-2 in 2019). The North Mill Creek mIBI of 55.8 at site 10-1 was unchanged from the mIBI of 55.3 in 2016 and only slightly lower than the mIBI of 55.8 in 2019. No poor or very poor responses were observed with mostly good responses. Mill Creek had two fair responses and North Mill Creek had three (Table 15).

Table 15. Selected macroinvertebrate assemblage attributes for sites sampled in the Upper Des Plaines Year 4 study area in 2020. Biological index scores selected metrics are shaded by narrative quality as follows: exceptional – blue; good (fully supporting) - green; fair (non-support) - yellow; poor (non-support) – orange; very poor – red (non-support); signatures of toxic and organic enrichment responses are based on Yoder and DeShon (2003).

Biological Assemblages – Fish

Forty-six (46) native and three (3) non-native fish species were collected along with four (4) hybrids in the Year 4 study area in 2020. The fish assemblage continued to be predominated by tolerant, moderately tolerant, and intermediate fish species (Table 16). Bluegill (*Lepomis macrochirus*), Bluntnose Minnow (*Pimephales notatus*), Spotfin Shiner (*Cyprinella spiloptera*), and Largemouth Bass (*Micropterus salmoides*) were the most numerous species collected in 2020. Common Carp (*Cyprinus carpio*), White Sucker (*Catostomus commersoni*), Northern Pike (*Esox lucius*), Channel Catfish (*Ictalurus punctatus*), and Largemouth Bass (*Micropterus salmoides*) predominated in terms of biomass. Of the top 15 species, five (5) are highly tolerant, two (2) moderately tolerant, and only one, Hornyhead Chub (*Nocomis biguttatus*) is intolerant. Many of these species are also common in low gradient and wetland influenced rivers while others are ubiquitous to rivers and streams throughout the region. The 2020 rankings are not substantially different than in 2016 or 2018 with the exception if certain species rankings.

Table 16. The fifteen most abundant species by number (left panel) by weight (right panel) collected in the upper Des Plaines mainstem in 2020. IL and OH tolerance assignments, numbers/weight (kg) collected, and percent collected by each (species with blank tolerance cells are intermediate).

Species	Tolerance		Number Collected	% By Number	Species	Tolerance		Weight Collected	% By Weight

Spotted Sucker			155	1.19	Gizzard Shad			0.59	1.28

I - Intolerant; M - Moderately Intolerant; P - Moderately Tolerant; T - Highly Tolerant

Stonecat Madtom (*Noturus flavus*), Hornyhead Chub, and Brook Silverside (*Labidesthes sicculus*) all increased in 2020. However, certain species that were collected in 2018 were either reduced in numbers or not present in the collections in 2020. Several species including Rock Bass (*Ambloplites rupestris*), Carmine Shiner (*Notropis percobromus*), Pirate Perch (*Aphredoderus sayanus*), Logperch (*Percina caprodes*), Blackside Darter (*Percina maculata*), and Sand Shiner (*Notropis stramineus*) were reduced by more than 50-90% compared to 2018. Blackchin Shiner (*Notropis heterodon*) numbered 48 in 2018, but were absent in 2020 in addition to Western Banded Killifish (*Fundulus diaphanus menona*) both of which are Illinois endangered species. The 2018 occurrence of Blackchin Shiner were likely related to restoration efforts in certain upper Des Plaines River watershed lakes (Bland 2013). A new species in 2020 is the invasive Round Goby (*Neogobius melanostomus*) which is a non-native of intercontinental origin that has been expanding from its original introduction in ship ballast water in the late 1980s. There were 21 individuals collected in 2020.

Figure 20. Two (2) Round Gobies (*Neogobius melanostomus*) collected at site 16-1 (RM 71.7) on August 14, 2020. Twenty-one (21) Round Goby individuals were collected at the four downstream most sites during the 2020 survey of the upper Des Plaines River mainstem.

Des Plaines River 2020 Fish Assemblage Results

Fish IBI (fIBI) scores are the mean of two sampling passes within the summer-early fall index period. The General Use Criterion of 41 was met or surpassed at only a single site in 2020 (Figure 21; Table 17). This is a decrease from the five (5) sites that met the General Use fIBI biocriterion in 2018 with scores at these sites being 2.0 to 7.0 less than in 2018. Only two sites (13-1 and 13-16) in the upper mainstem had a 4.0 or greater departure from the General Use fIBI biocriterion, while the other two (sites 16-16 and 16-7) had 1.5 unit departures. The fIBI scores were lowest in the upper most reach of the mainstem as in 2016 and 2018. Scores increased into the mid to high 30s downstream of the Wetland Research riffle through the be observed downstream from the Libertyville and Mundelein WWTPs then recovering to meeting the fIBI General Use biocriterion at site 16-2 (RM 75.40) downstream from the DPW mainstem

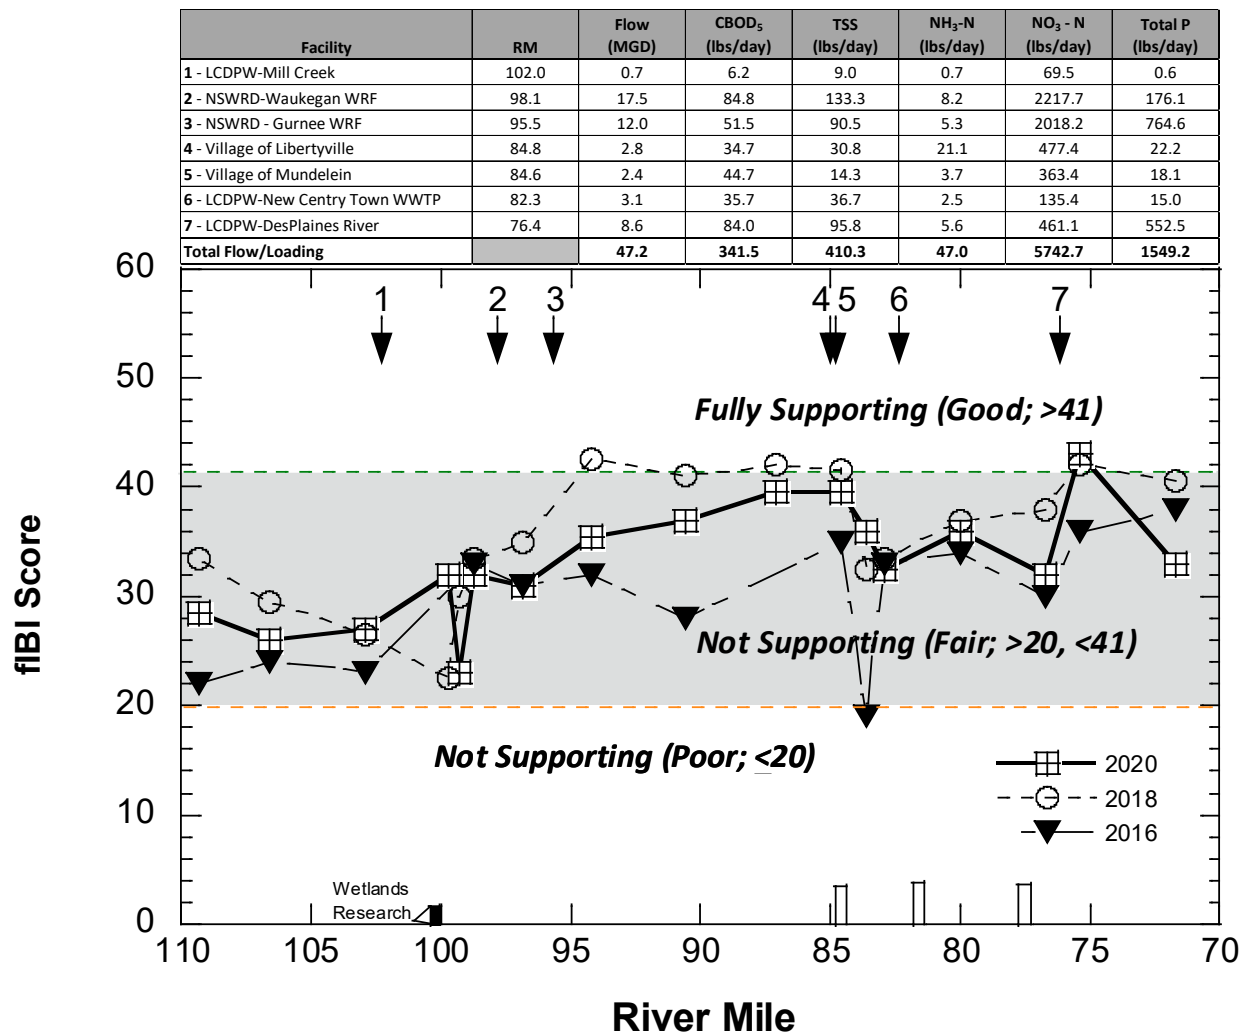

Figure 21. Illinois fish IBI (fIBI) scores for the upper Des Plaines River in 2016, 2018, and 2020. IEPA thresholds for determining full support, non-support-fair, and non-support poor of the General Use for aquatic life are indicated by dashed lines and grey shading. A key to sources (arrows and numbers) is in the table above the figure along with flows and loads from each.

where habitat and flow conditions were improved. Localized declines continued to DesPlaines WWTP. The Modified Index of Well-Being (MIwb) has no formal biocriteria in Illinois, but using the Ohio biocriteria it attained the Ohio equivalent of the General Use at 16 of the 17 sites, and was rated fair only at site 16-1 (Figure 23). Overall, the MIwb was improved at most sites compared to the 2016 and 2018 surveys, and attained an excellent narrative (MIwb >9.0) at sites 13-18 and 13-3. Although the MIwb excludes highly tolerant species from the biomass and numbers metrics, it can be increased by moderately tolerant and intermediate fish species some of which can tolerate moderate amounts of pollution (Yoder and Smith 1999). With only a very few exceptions the MIwb precedes the IBI in terms of showing recovery after stressor abatements have been implemented. In the upper DesPlaines River mainstem it is likely responding positively to the moderate organic and nutrient enrichment that emanates from the upper modified reach.

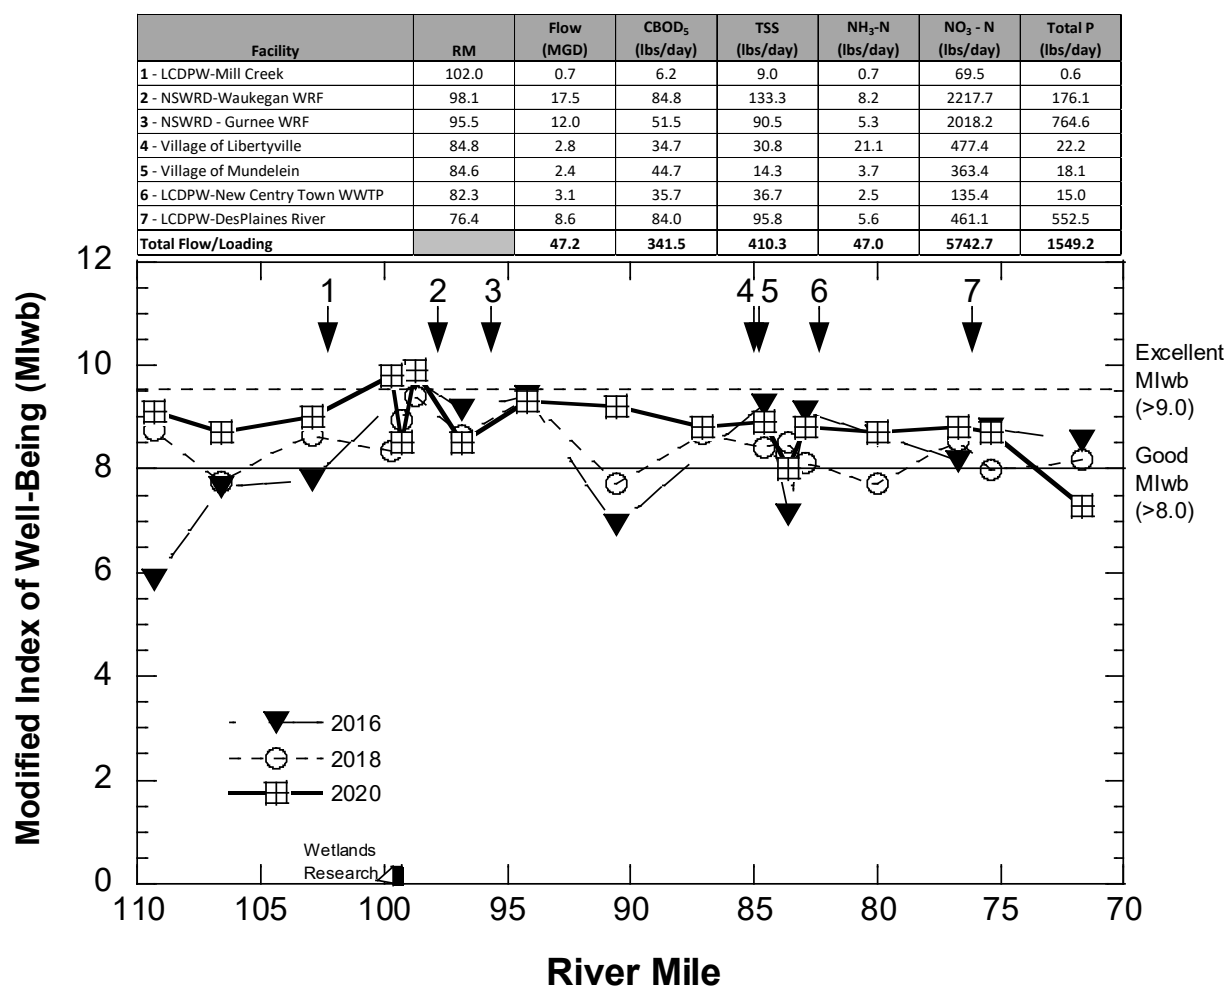

Figure 22. Modified Index of Well-Being (MIwb) for the upper Des Plaines River in 2016, 2018, and 2020. A key to sources (arrows and numbers) is in the table above the figure along with flow and loads from each.

Table 17 lists the fIBI, selected fIBI metrics, and other fish assemblage attributes one of which exhibits key biological response signatures associated with both organic enrichment and toxic impacts, %DELT anomalies. Metrics and attributes that had values predominantly in the good range were %DELT anomalies with six (6) sites recording zero (0) anomalies. The %tolerant species ranged from 23.9-31.8% with 13 sites in the good range and the remainder fair. Intolerant species ranged from 1-4 with good values at eight (8) sites, fair values at five (5) sites, and the remaining four (4) sites being poor (<1). The poorest performing metric continues to be the %mineral spawners, ranging from 1.20-22.06% with nine (9) sites having poor percentages and the remainder in the fair range. These results were mostly unchanged from 2018.

Mill Creek and North Mill Creek 2020 Fish Assemblage Results

Fish were sampled at a single site each in Mill Creek (11-2) and two sites in North Mill Creek (10-7 and 10-1) in 2020. Mill Creek (11-2) had a fair fIBI score and North Mill Creek had fIBI scores that were at (10-7) and within (10-1) the poor narrative (Table 17). The 2020 fIBI of 29.5

Table 17. Selected fish assemblage attributes for sites sampled in the Upper Des Plaines Year 4 study area in 2020. Biological index scores selected metrics are shaded by narrative quality as follows: exceptional – blue; good (fully supporting) - green; fair (non-support) - yellow; poor (non-support) – orange; very poor – red (non-support); signatures of toxic and organic enrichment responses are based on Yoder and DeShon (2003).

in Mill Creek at site 11-2 was only slightly lower than the 2016 result that had a fair fIBI of 31.0, but better than the poor fIBI of 23 in 2019. The North Mill Creek poor fIBI of 19.5 at site 10-1 was similar to the fIBI of 22.0 in 2016 and the poor fIBI of 18.0 in 2019. The barely fair fIBI of 20.5 at site 10.7 was only a slight improvement over the poor fIBI of 18 in 2019 (site 10-7 was not sampled in 2016). Mill Creek at 11-2 had two poor responses and North Mill Creek site 10-7 had two poor and two very poor responses and 10-1 had four poor and one very poor response signature (Table 17).

SYNTHESIS

The baseline biological condition of the upper Des Plaines River mainstem has been shaped by the naturally low gradient and wetland-origins of the region. The current condition of the biological assemblages reflects changes that have altered these natural features mostly via hydrological and physical alterations in the upper watershed related to agricultural and suburban development adding more intensive urban development in the lower portions of the study area. Altered hydrology and habitat alterations in the upper mainstem and greater watershed continue to impair the biological assemblages due to the sluggish flows, excessive siltation, substrate embeddedness, nuisance growths of algae and macrophytes, and indicators of excessive organic and nutrient enrichment. The sources are primarily nonpoint in origin that are further exacerbated by the altered flows and habitat in the upper 10 miles of the mainstem. The longitudinal pattern in biological index scores and several chemical parameters strongly suggest that this impact is exported downstream into the upper portion of the effluent dominated reach of the mainstem with the pollution footprint varying somewhat between years. Overall, biological performance improved from 2016 to 2018 with the longest reach of full attainment occurring over nearly 10 miles from site 13-1 (RM 94.2) to site 16-7 (RM 84.6) where habitat quality improved as was the increased flow with the introduction of treated wastewater from several point sources. Despite the backsliding observed in 2020 at four of the former fully attaining sites, the continuing attainment at site 16-2 (RM 75.4) is downstream of all wastewater inputs. Of the four (4) sites that did not attain the full General Use in 2020 that were in attainment in 2018, three (3) did not significantly depart from the fIBI which was the most limiting of the two biological indices.

The Area of Degradation and Area of Attainment Values (ADV/AAV; ; Yoder et al. 2005, 2019) were used to quantify the extent and severity of biological impairment and the extent of changes that have been taken place in the upper Des Plaines mainstem 2016, 2018, and 2020. The ADV/AAV is calculated individually for each index and was done here for the fIBI and mIBI (Figure 22) and by separating the upper 10 mile habitat and hydrologically modified reach from the remainder of the mainstem downstream to the Lake-Cook Co. line with the upstream boundary of the lower reach at the confluence with Mill Creek and the entry of significant volumes of treated wastewater. The ADVs for the fIBI and the mIBI reveal the severity and extent of impairment of the General Use for aquatic life in the upper mainstem in 2020 that was essentially unchanged from that observed in 2016 and 2018. It continues to reflect the chemical, hydrological, and habitat alterations in this reach. In the lower reach downstream from Mill Creek no AAV was observed in 2020 due to the fIBI failing to meet the General Use at any except a single site in 2020. Though the fIBI failed to attain the General Use criterion in 2020 resulting in an increase in the ADV from 2018, it was smaller than in 2016 (Figure 22). The macroinvertebrate AAV declined slightly in 2020 from 2018 due to three (3) fewer sites attaining the mIBI General Use biocriterion, but the ADV remained unchanged. The ADV continues to reflect the non-attainment of both the fish and macroinvertebrate assemblages in the upper watershed and the overall non-attainment in the lower watershed in 2020. The overall trajectory is unchanged in the modified upper reach and a slight improvement from

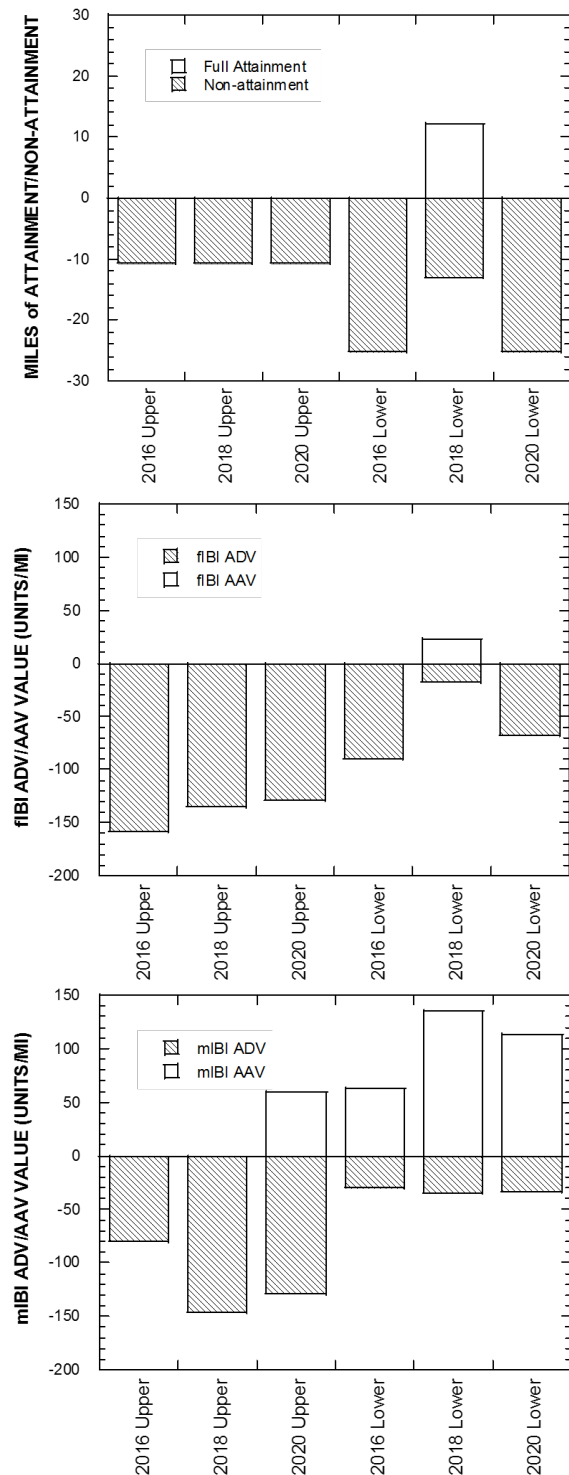

Figure 23. Area of Degradation (ADV; cross hatched) and Area of Attainment (AAV; open shading) values in the upper reach and remaining lower reach of the upper Des Plaines River in 2016, 2018, and 2020 (upper and middle panels). The miles of full and non-attainment appear in the lower panel.

2016. The miles of attainment reflecting more of a pass/fail assessment increased between 2018 and 2020 to levels similar to 2016 in both reaches of the mainstem.

NE Illinois IPS thresholds for water and sediment chemistry and physical habitat attributes were used in concert with other variables to determine causes of impairment. The thresholds across five narrative categories (excellent, good, fair, poor, and very poor) provides a graded approach to the assignment of causes and sources for the Illinois General Use for aquatic life impairments. These tools were integrated with previously used tools and indicators to assign associated causes to the biological impairments observed in 2020 and offers the semblance of a tiered aquatic life use (AQLU) stratification of goals to support local restoration and protection efforts by the respective watershed groups and stakeholders.

The biological criteria for fish and macroinvertebrates used by Illinois EPA (2020) establish the thresholds by which impaired sites and reaches are determined. The assignment of causes in this analysis generally attempts to follow the overall intent of the Illinois Integrated Report assessment guidelines, but is supplemented by the more extensive biological effect thresholds provided by the IPS tools and dashboard (MBI 2020a). The delineation of causes and sources was based on integrating and synthesizing the preceding analyses of categorical and parameter-specific stressor threshold exceedances. The most influential of these are included in Table 19 along with the fish and macroinvertebrate IBI scores. Habitat alteration is represented by the QHEI and the QHEI modified:good attributes ratio, D.O. includes the minimum measured by Datasondes, the effect of nutrient enrichment by the diel D.O. swing narrative, the nutrient enrichment effect status, the new IPS nutrient index, new IPS

Table 18. Key chemical, physical, and biological response indicators of impairment observed at each site in the Upper Des Plaines River study area in 2020. The causes associated with biological impairments are drawn from analyses of habitat, nutrient effects, chemical IPS and other threshold exceedances, sediment chemical IPS exceedances, and biological response signatures. Causes of impairment are classified as fair, poor, or very poor in accordance with the exceedance of corresponding thresholds. See footnotes for table references and biological, physical, and chemical threshold intervals. IPS restorability score are provided for non- and partially supporting sites and susceptibility and threat scores are provided for fully supporting sites.

chemical threshold exceedances for water and sediment, and biological response signatures for organic enrichment and toxic tolerant indicators. The rationale for listing the predominant causal categories in 2020 follows:

- **Macro Habitat Related** (64 observations; weighted frequency of 39.5%) – the number of high influence or moderate influence poor or good attributes in the QHEI attributes matrix (Table 13), a fair, poor, or very poor QHEI score, or an IPS habitat factor;
- **Organic/Nutrient Enrichment** (66 observations; weighted frequency of 36.5%) – any ammonia-N, total P, nitrate-N, or TKN median value exceedance of IPS fair, poor, or very poor (Table 10; TKN used as a proxy for BOD per Miltner 2018), and any fair, poor, or very poor organic enrichment response signature (Tables 15 and 17);
- **D.O. Related** (22 observations; weighted frequency of 13.8%) – any fair, poor, or very poor maximum of minimum D.O. or diel D.O. swing from continuous measurements (Table 12).
- **Urban Related** (26 observations; weighted frequency of 10.2%) – any chloride, conductivity, or TSS median value exceedance of IPS fair, poor, or very poor threshold in Table 10 and any IPS derived urban land use variable exceeding fair, poor, or very poor threshold.
- **Toxics** (0 observations; weighted frequency 0.0%) – any exceedance of Illinois WQC or IPS fair, poor, or very poor thresholds for a toxic compound (none recorded) or any toxic response signature (Table 15 and 17).

Macro Habitat Related was the most pervasive cause followed closely by Organic/Nutrient Enrichment based on the weighted frequency of each. D.O. related issues at 13.8% comprised about one-third of the observations of either Macro Habitat Related or Organic/Nutrient Enrichment issues with Urban Related causes at 10.2%. The Macrohabitat Related, Organic/Nutrient Enrichment, and D.O. Related had the only poor and very poor values that were primarily observed in the 10 mile long modified upper reach upstream from the Wetland Research Riffle with observations of very poor and poor Organic/Nutrient Enrichment issues observed immediately downstream of the Wetland Research Riffle. Very poor and poor nutrient exceedances occurred sporadically in the middle and lower reaches of the mainstem. Very poor and poor ammonia-N levels occurred downstream from the Libertyville and Mundelein WTPs, but none of these values would have exceeded the Illinois WQC for ammonia-N. Elevated levels of Nitrate-N and total P in the poor and most frequently in the fair range were primarily observed in the effluent influenced reaches of the middle and lower mainstem. Urban related causes exceeding mostly fair thresholds occurred mostly in the middle and lower mainstem, but poor exceedances of the Impervious Cover-30 meter buffer occurred at the two upstream most sites. These results are similar to the 2018 results although the 2020 causal categories were further refined in 2020.

The introduction of large volumes of treated municipal wastewater continues to benefit the Des Plaines River and aides in offsetting detrimental impacts that are exported downstream from the modified upper reach of the mainstem. Even with the lower FBI scores in 2020, the longitudinal pattern was the same – consistent incremental improvement downstream from

the Wetland Research riffle and seemingly independent of the entry of large volumes of treated wastewater. This and the accumulation of more poor and very poor exceedances of IPS and other thresholds in the upper modified reach points to nonpoint sources being exacerbated by the habitat and hydrological modifications in the upper watershed as the major limiting sources to aquatic life.

Only a single site (16-2) was in full attainment of the General Use for aquatic life in 2020 down from five sites in 2018 all in the effluent dominated reach of the study area. Partial attainment was observed in the stretch between site 13-1 (RM 94.2) and site 16-3 (RM 76.70) with the exception of site 16-8 (RM 82.90) which was non-fair. Each of these sites were limited by non-attainment of the fIBI biocriterion with most scores marginally lower than in 2018. The sites immediately upstream and downstream from the Libertyville and Mundelein WWTPs missed full attainment by only 1.5 units. The discovery of Round Goby at the four (4) downstream most sites also adds an unknown factor for the aquatic assemblages. With no barriers until the Wetland Research riffle the species will likely move farther upstream, possibly having deleterious effects on the already marginal fish assemblage. The biological results downstream from the entry of treated wastewater at site 13-3 were better both in terms of AQLU status and the fIBI and mIBI scores than at the five upstream most sites that were in non-fair and non-poor attainment status and with four (4) of five (5) fIBI scores in the poor range.

Instructions for scoring the alternate cover metric: Each cover type should receive a score of between 0 and 3, where: 0 = Cover type absent; 1 = cover type in very small amounts or if more common of marginal quality; 2 = cover type present in moderate amounts, but not of highest quality or in small amounts of highest quality; 3 = cover type of highest quality in moderate of greater amounts. Examples of highest quality include, very large boulders in deep or fast water, large diameter logs that are stable, well developed rootwads in deep / fast water, or deep, well-defined, functional pools.

Stream Drawing:

Instructions for scoring the alternate cover metric: Each cover type should receive a score of between 0 and 3, where: 0 = Cover type absent; 1 = cover type in very small amounts or if more common of marginal quality; 2 = cover type present in moderate amounts, but not of highest quality or in small amounts of highest quality; 3 = cover type of highest quality in moderate of greater amounts. Examples of highest quality include, very large boulders in deep or fast water, large diameter logs that are stable, well developed rootwads in deep / fast water, or deep, well-defined, functional pools.

Instructions for scoring the alternate cover metric: Each cover type should receive a score of between 0 and 3, where: 0 = Cover type absent; 1 = cover type in very small amounts or if more common of marginal quality; 2 = cover type present in moderate amounts, but not of highest quality or in small amounts of highest quality; 3 = cover type of highest quality in moderate of greater amounts. Examples of highest quality include: very large boulders in deep or fast water, large diameter logs that are stable, well developed rootwads in deep / fast water, or deep, well-defined, functional pools.

Instructions for scoring the alternate cover metric: Each cover type should receive a score of between 0 and 3, where: 0 = Cover type absent; 1 = cover type in very small amounts or if more common of marginal quality; 2 = cover type present in moderate amounts, but not of highest quality or in small amounts of highest quality; 3 = cover type of highest quality in moderate or greater amounts. Examples of highest quality include, very large boulders in deep or fast water, large diameter logs that are stable, well developed rootwads in deep / fast water, or deep, well-defined, functional pools.

Instructions for scoring the alternate cover metric: Each cover type should receive a score of between 0 and 3, where: 0 = Cover type absent; 1 = cover type in very small amounts or if more common of marginal quality; 2 = cover type present in moderate amounts, but not of highest quality or in small amounts of highest quality; 3 = cover type of highest quality in moderate of greater amounts. Examples of highest quality include, very large boulders in deep or fast water, large diameter logs that are stable, well developed rootwads in deep / fast water, or deep, well-defined, functional pools.

Major Suspected Sources of Impacts (Check All That Apply):

APPENDIX D

D-1: FIT Factors for Deriving Primary, Secondary, and Tertiary Causes of Impairment

Appendix D-1: Development of FIT Factors for Deriving Primary, Secondary, and Tertiary Causes of Impairment

The NE IL IPS thresholds were developed for the primary nutrient and nutrient-related parameters based on grab sample data. The thresholds were based on relationships between that data and stressor-specific sensitive fish species and macroinvertebrate taxa. The relationship between the sensitive species/taxa with the FBI and mBI supported benchmarking these thresholds to the General Use criteria and an “Excellent” level of biological performance.

The FIT weighting score influences the categories of narrative condition (i.e., very poor, poor, or fair) each cause of impairment is placed. Each stressor is ranked from 0.1 (excellent) to 10 (very poor) based on the respective relationships with the number of stressor-sensitive fish species

Appendix Table D-1. FIT weighting scores based on FIT coefficients.

FIT (< 0.10) X 1;
FIT (> 0.10 – <0.3) X 0.8
FIT (> 0.30 – < 1.0) X 0.6
FIT (> 1.00 – < 3.0) X 0.5
FIT (> 3.00 – < 10.0) X 0.2
FIT (> 10.0) X 0.1

or macroinvertebrate taxa as the response variable with a particular stressor. Where the association is very strong (i.e., FIT value < 0.1) it means there were few outliers and a stronger power of prediction. The weighting factor is 1 and stressors that scored as very poor are still considered to be predictive of very poor biological assemblages. As the FIT value increases (i.e., >0.1 to 0.3) it signals increased variability (more outliers are observed). The weighting factor declines to 0.8 and a stressor value of 9 (very poor) would be down weighted to a score of 7.2 (poor) because the stress:response relationship had more outliers. While the ability to distinguish poor vs. very poor assemblages is reduced, it still reflects a severe impairment. A FIT value of >0.3-1 indicates a weaker causative relationship and has lower weighting factor (X 0.6). This would change a stressor score of 9 (very poor) to a score of 5.4 (fair). Parameters with FIT values of >3 were not used to identify causes of impairment. A summary of FIT values for 69 variables is in Appendix Table E-2.

Stressor relationships can become stronger as more data is added to the IPS databases hence the need for continued monitoring. Some parameters that have weak FIT scores are because of a lack of data along a complete stressor gradient. For example, there are fewer data points at excellent biological sites for parameters such as sediment PAHs and sediment metals. This weakens the FIT values for the excellent narrative range thus in these situations only a good narrative threshold is derived. There are other important variables (e.g., benthic chlorophyll a) where the current datasets are insufficient to develop a ranking thus highlighting the need to build up the dataset.

The severity of effect of some stressors (e.g., FIT Scores <0.1) could possibly mask the effects of other stressors. As more data is collected and as some of the more prevalent stressors are abated, the influence of masked stressors may become more evident. As such, the FIT values and scores could change in future iterations of the IPS. More data will also improve the accuracy of assigning species and taxa as sensitive or tolerant to a particular stressor.

Appendix Table D-2. FIT values based on the deviation between ambient stressor rank vs. predicted stressor rank based on fish species or macroinvertebrate taxa for streams in the NE IL IPS study area. The algorithm for FIT calculation is summarized in the text. The cell shading is related to FIT weighting coefficients: 1.0; 0.8; 0.6; 0.5; 0.2.
